Web Services

15-213 / 18-213: Introduction to Computer Systems 22ndLecture, April 10, 2012

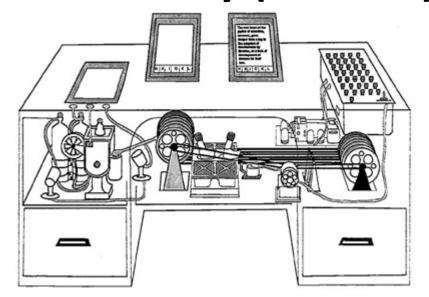

Instructors:

Todd C. Mowry and Anthony Rowe

Today

- ■HTTP and Static Content
- ■Serving Dynamic Content
- Proxies

Web History (seminal)

"Consider a future device for individual use, which is a sort of mechanized private file and library. It needs a name, and to coin one at random, "memex" will do. A memex is a device in which an individual stores all his books, records, and communications, and which is mechanized so that it may be consulted with exceeding speed and flexibility. It is an enlarged intimate supplement to his memory."

1945:

- Vannevar Bush, "As we may think", Atlantic Monthly, July, 1945
 - Describes the idea of a distributed hypertext system
 - A "memex" that mimics the "web of trails" in our minds

Web History

1989:

- Tim Berners-Lee (CERN) writes internal proposal to develop a distributed hypertext system
 - Connects "a web of notes with links"
 - Intended to help CERN physicists in large projects share and manage information

1990:

Tim BL writes a graphical browser for Next machines

Web History (cont)

1992

- NCSA server released
- 26 WWW servers worldwide

1993

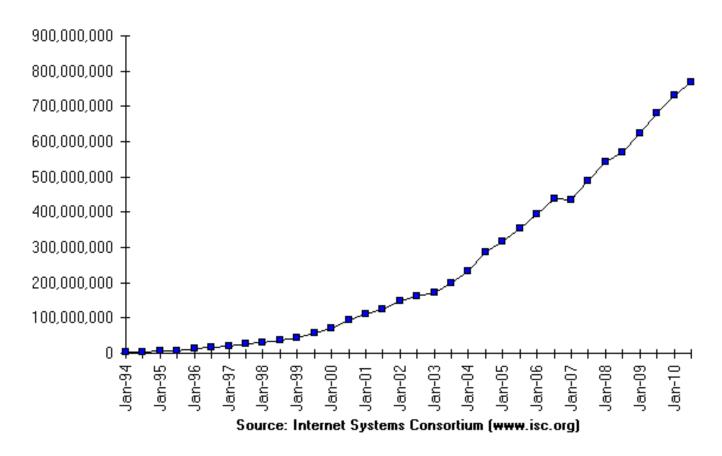

- Marc Andreessen releases first version of NCSA Mosaic browser
- Mosaic version released for (Windows, Mac, Unix)
- Web (port 80) traffic at 1% of NSFNET backbone traffic
- Over 200 WWW servers worldwide

1994

 Andreessen and colleagues leave NCSA to form "Mosaic Communications Corp" (predecessor to Netscape)

Internet Hosts

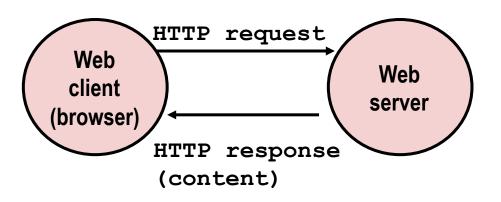

Internet Domain Survey Host Count

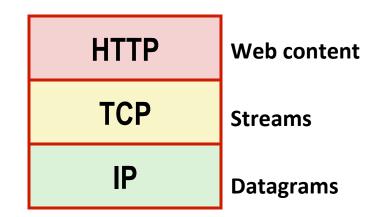

How many of the 2³² IP addresses have registered domain names?

Web Servers

- Clients and servers communicate using the HyperText Transfer Protocol (HTTP)
 - Client and server establish TCP connection
 - Client requests content
 - Server responds with requested content
 - Client and server close connection (eventually)
- Current version is HTTP/1.1
 - RFC 2616, June, 1999.

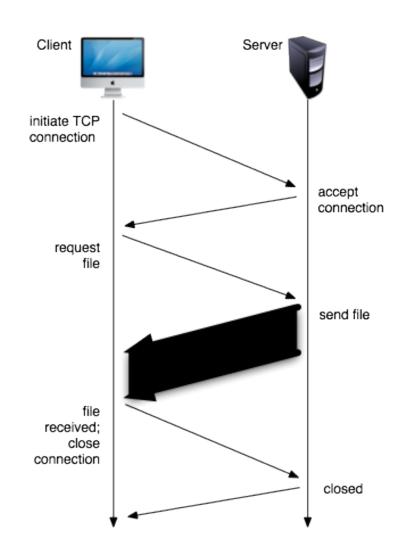

http://www.w3.org/Protocols/rfc2616/rfc2616.html

Client-server web communication

- Clients and servers communicate using the HyperText Transfer Protocol (HTTP)
 - Client and server establish TCP connection
 - Client requests content
 - Server responds with requested content
 - Client and server close connection (usually)
- ■Current version is HTTP/1.1
 - RFC 2616, June, 1999
 - http://www.ietf.org/rfc/rfc2616.txt

Web Content

Web servers return content to clients

 content: a sequence of bytes with an associated MIME (Multipurpose Internet Mail Extensions) type

Example MIME types

text/html HTML document

text/plain
Unformatted text

application/postscript Postcript document

image/gif
Binary image encoded in GIF format

image/jpeg
Binary image encoded in JPEG format

Static and Dynamic Content

- The content returned in HTTP responses can be either static or dynamic
 - Static content: content stored in files and retrieved in response to an HTTP request
 - Examples: HTML files, images, audio clips
 - Request identifies which content file
 - Dynamic content: content produced on-the-fly in response to an HTTP request
 - Example: content produced by a program executed by the server on behalf of the client
 - Request identifies which file containing executable code
- Bottom line: (most) Web content is associated with a file that is managed by the server

URLs and how clients and servers use them

- Unique name for a file: URL (Universal Resource Locator)
- Example URL: http://www.cmu.edu:80/index.html
- Clients use *prefix* (http://www.cmu.edu:80) to infer:
 - What kind (protocol) of server to contact (HTTP)
 - Where the server is (www.cmu.edu)
 - What port it is listening on (80)
- Servers use suffix (/index.html) to:
 - Determine if request is for static or dynamic content.
 - No hard and fast rules for this
 - Convention: executables reside in cqi-bin directory
 - Find file on file system
 - Initial "/" in suffix denotes home directory for requested content.
 - Minimal suffix is "/", which server expands to configured default filename (usually, index.html)

Anatomy of an HTTP Transaction

unix> telnet www.cmu.edu 80
Trying 128.2.10.162...
Connected to www.cmu.edu.
Escape character is '^]'.

GET / HTTP/1.1
host: www.cmu.edu

Client: open connection to server Telnet prints 3 lines to the terminal

Client: request line

Client: required HTTP/1.1 HOST header Client: empty line terminates headers.

HTTP/1.1 301 Moved Permanently Server: response line

Location: http://www.cmu.edu/index.shtml Client should try again

Connection closed by foreign host. Server: closes connection

unix> Client: closes connection and terminates

Anatomy of an HTTP Transaction, Take 2

```
Client: open connection to server
unix> telnet www.cmu.edu 80
                                          Telnet prints 3 lines to the terminal
Trying 128.2.10.162...
Connected to www.cmu.edu.
Escape character is '^]'.
GET /index.shtml HTTP/1.1
                                         Client: request line
                                         Client: required HTTP/1.1 HOST header
host: www.cmu.edu
                                         Client: empty line terminates headers.
HTTP/1.1 200 OK
                                          Server: responds with web page
Date: Fri, 29 Oct 2010 19:41:08 GMT
Server: Apache/1.3.39 (Unix) mod pubcookie/3.3.3 ...
Transfer-Encoding: chunked
Content-Type: text/html
                                         Lots of stuff
Connection closed by foreign host. Server: closes connection
                                          Client: closes connection and terminates
unix>
```

HTTP Requests

- HTTP request is a request line, followed by zero or more request headers
- Request line: <method> <uri> <version>
 - <method> is one of GET, POST, OPTIONS, HEAD, PUT,
 DELETE, or TRACE
 - <uri>is typically URL for proxies, URL suffix for servers
 - A URL is a type of URI (Uniform Resource Identifier)
 - See http://www.ietf.org/rfc/rfc2396.txt
 - <version> is HTTP version of request (HTTP/1.0 or HTTP/1.1)

HTTP Requests (cont)

HTTP methods:

- GET: Retrieve static or dynamic content
 - Arguments for dynamic content are in URI
 - Workhorse method (99% of requests)
- POST: Retrieve dynamic content
 - Arguments for dynamic content are in the request body
- OPTIONS: Get server or file attributes
- HEAD: Like GET but no data in response body
- PUT: Write a file to the server!
- DELETE: Delete a file on the server!
- TRACE: Echo request in response body
 - Useful for debugging

Request headers: <header name>: <header data>

Provide additional information to the server

HTTP Versions

Major differences between HTTP/1.1 and HTTP/1.0

- HTTP/1.0 uses a new connection for each transaction
- HTTP/1.1 also supports persistent connections
 - multiple transactions over the same connection
 - Connection: Keep-Alive
- HTTP/1.1 requires HOST header
 - Host: www.cmu.edu
 - Makes it possible to host multiple websites at single Internet host
- HTTP/1.1 supports chunked encoding (described later)
 - Transfer-Encoding: chunked
- HTTP/1.1 adds additional support for caching

HTTP Responses

- HTTP response is a response line followed by zero or more response headers, possibly followed by data
- Response line:

```
<version> <status code> <status msg>
```

- <version> is HTTP version of the response
- <status code> is numeric status
- <status msg> is corresponding English text

200 OK Request was handled without error

301 Moved Provide alternate URL

403 Forbidden Server lacks permission to access file

404 Not found Server couldn't find the file

Response headers: <header name>: <header data>

- Provide additional information about response
- Content-Type: MIME type of content in response body
- Content-Length: Length of content in response body

GET Request to Apache Server From Firefox Browser

URI is just the suffix, not the entire URL

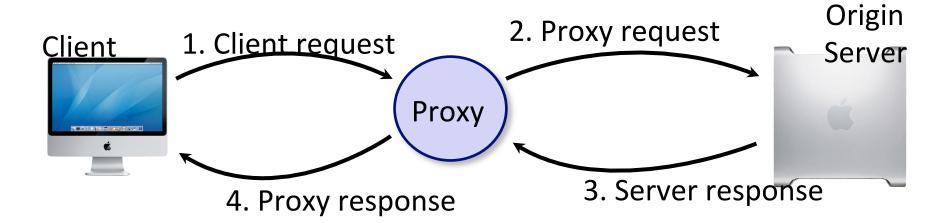

```
GET /~bryant/test.html HTTP/1.1
Host: www.cs.cmu.edu
User-Agent: Mozilla/5.0 (Windows; U; Windows NT 6.0; en-US; rv:
1.9.2.11) Gecko/20101012 Firefox/3.6.11
Accept: text/html,application/xhtml+xml,application/
xml;q=0.9,*/*;q=0.8
Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip,deflate
Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 115
Connection: keep-alive
CRLF (\r\n)
```

GET Response From Apache Server

```
HTTP/1.1 200 OK
Date: Fri, 29 Oct 2010 19:48:32 GMT
Server: Apache/2.2.14 (Unix) mod ssl/2.2.14 OpenSSL/0.9.7m
mod pubcookie/3.3.2b PHP/5.3.1
Accept-Ranges: bytes
Content-Length: 479
Keep-Alive: timeout=15, max=100
Connection: Keep-Alive
Content-Type: text/html
<html>
<head><title>Some Tests</title></head>
<body>
<h1>Some Tests</h1>
</body>
</html>
```

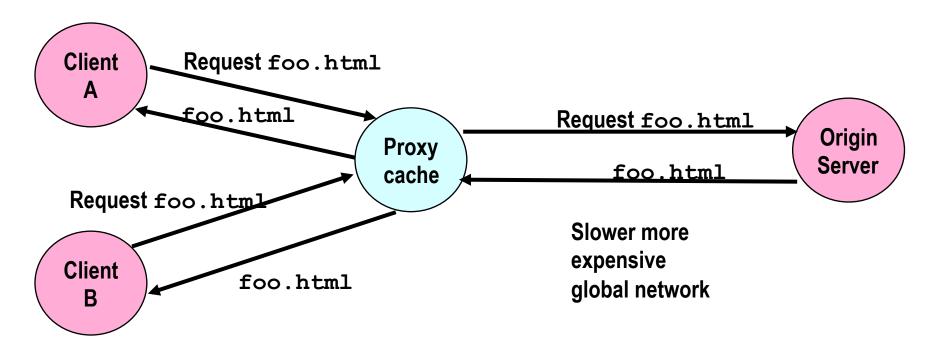

Proxies

- ■A proxy is an intermediary between a client and an origin server
 - To the client, the proxy acts like a server
 - To the server, the proxy acts like a client

Why Proxies?

- Can perform useful functions as requests and responses pass by
 - Examples: Caching, logging, anonymization, filtering, transcoding

Fast inexpensive local network

Two types of web proxy

Explicit (browser-known) proxies

- Used by configuring browser to send requests to proxy
- Each request specifies entire URL
 - allowing proxy to know target server

Transparent proxies

- Browser/client behaves as though there is no proxy
- Proxy runs on network component in route between client and server
 - intercepting and interposing on web requests

Tiny Web Server

■ Tiny Web server described in text

- Tiny is a sequential Web server
- Serves static and dynamic content to real browsers
 - text files, HTML files, GIF and JPEG images
- 226 lines of commented C code
- Not as complete or robust as a real web server

Tiny Operation

- Accept connection from client
- Read request from client (via connected socket)
- Split into method / uri / version
 - If not GET, then return error
- If URI contains "cgi-bin" then serve dynamic content
 - (Would do wrong thing if had file "abcgi-bingo.html")
 - Fork process to execute program
- Otherwise serve static content
 - Copy file to output

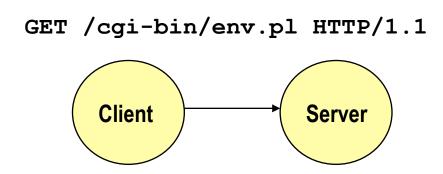

Tiny Serving Static Content

```
/* Send response headers to client */
                                                      From tiny.c
   get filetype(filename, filetype);
   sprintf(buf, "HTTP/1.0 200 OK\r\n");
   sprintf(buf, "%sServer: Tiny Web Server\r\n", buf);
   sprintf(buf, "%sContent-length: %d\r\n", buf, filesize);
   sprintf(buf, "%sContent-type: %s\r\n\r\n",
           buf, filetype);
   Rio writen(fd, buf, strlen(buf));
   /* Send response body to client */
   srcfd = Open(filename, O RDONLY, 0);
   srcp = Mmap(0, filesize, PROT READ, MAP PRIVATE, srcfd, 0);
   Close(srcfd);
   Rio writen(fd, srcp, filesize);
   Munmap(srcp, filesize);
```

- Serve file specified by filename
- Use file metadata to compose header
- "Read" file via mmap
- Write to output

Serving Dynamic Content

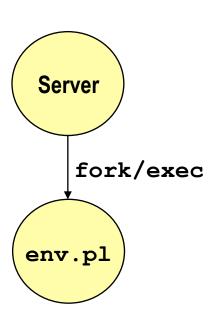

- Client sends request to server
- If request URI contains the string "/cgi-bin", then the server assumes that the request is for dynamic content

Serving Dynamic Content (cont)

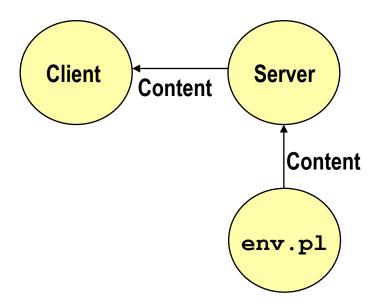

The server creates a child process and runs the program identified by the URI in that process

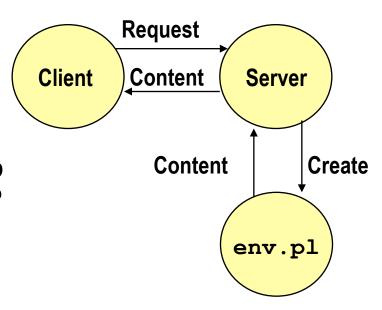

Serving Dynamic Content (cont)

- The child runs and generates the dynamic content
- The server captures the content of the child and forwards it without modification to the client

Issues in Serving Dynamic Content

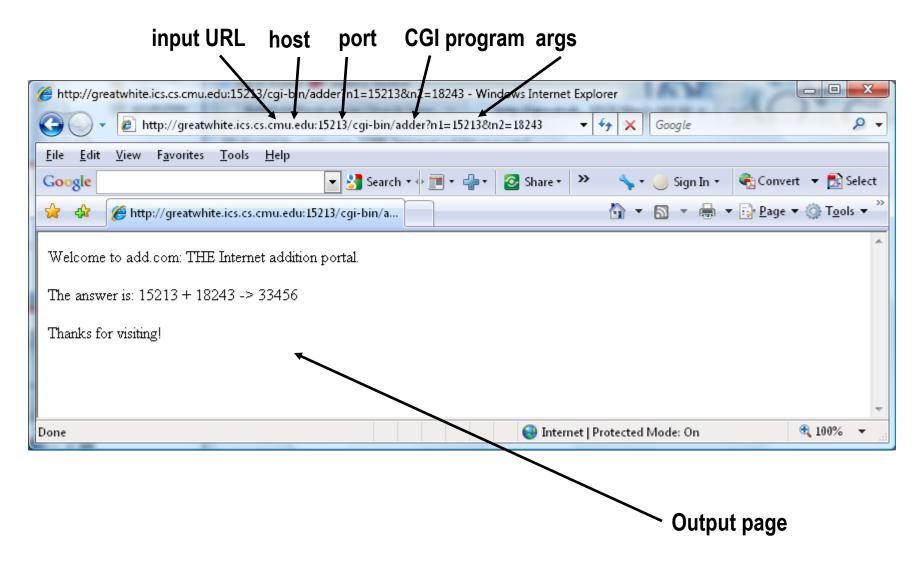

- How does the client pass program arguments to the server?
- How does the server pass these arguments to the child?
- How does the server pass other info relevant to the request to the child?
- How does the server capture the content produced by the child?
- These issues are addressed by the Common Gateway Interface (CGI) specification.

CGI

- Because the children are written according to the CGI spec, they are often called CGI programs.
- Because many CGI programs are written in Perl, they are often called CGI scripts.
- However, CGI really defines a simple standard for transferring information between the client (browser), the server, and the child process.

The add.com Experience

- Question: How does the client pass arguments to the server?
- Answer: The arguments are appended to the URI
- Can be encoded directly in a URL typed to a browser or a URL in an HTML link
 - http://add.com/cgi-bin/adder?n1=15213&n2=18243
 - adder is the CGI program on the server that will do the addition.
 - argument list starts with "?"
 - arguments separated by "&"
 - spaces represented by "+" or "%20"

- URL:
 - cgi-bin/adder?n1=15213&n2=18243
- Result displayed on browser:

Welcome to add.com: THE Internet addition portal. The

answer is: 15213 + 18243 -> 33456

Thanks for visiting!

- Question: How does the server pass these arguments to the child?
- Answer: In environment variable QUERY_STRING
 - A single string containing everything after the "?"
 - For add: QUERY STRING = "n1=15213&n2=18243"

From adder.c

```
if ((buf = getenv("QUERY_STRING")) != NULL) {
   if (sscanf(buf, "n1=%d&n2=%d\n", &n1, &n2) == 2)
      sprintf(msg, "%d + %d -> %d\n", n1, n2, n1+n2);
   else
      sprintf(msg, "Can't parse buffer '%s'\n", buf);
}
```

Additional CGI Environment Variables

General

- SERVER SOFTWARE
- SERVER NAME
- GATEWAY INTERFACE (CGI version)

Request-specific

- SERVER PORT
- REQUEST METHOD (GET, POST, etc)
- QUERY STRING (contains GET args)
- REMOTE_HOST (domain name of client)
- REMOTE_ADDR (IP address of client)
- CONTENT_TYPE (for POST, type of data in message body, e.g., text/html)
- CONTENT_LENGTH (length in bytes)

Even More CGI Environment Variables

- In addition, the value of each header of type *type* received from the client is placed in environment variable HTTP *type*
 - Examples (any "-" is changed to "_"):
 - HTTP ACCEPT
 - HTTP HOST
 - HTTP_USER_AGENT

- Question: How does the server capture the content produced by the child?
- Answer: The child generates its output on stdout. Server uses dup2 to redirect stdout to its connected socket.
 - Notice that only the child knows the type and size of the content. Thus the child (not the server) must generate the corresponding headers.

```
linux> telnet greatwhite.ics.cs.cmu.edu 15213
  Trying 128.2.220.10...
  Connected to greatwhite.ics.cs.cmu.edu (128.2.220.10).
_ _Escape character is '^l'. _ _ _ _
  GET /cgi-bin/adder?n1=5&n2=27 HTTP/1.1
                                          HTTP request sent by client
  host: greatwhite.ics.cs.cmu.edu
 <CRLF>
  HTTP/1.0 200 OK
                                    HTTP response generated by the server
  Server: Tiny Web Server
 Content-length: 109
  Content-type: text/html
  Welcome to add.com: THE Internet addition portal.
  p>The answer is: 5 + 27 -> 32
                                          HTTP response generated by
                                          the CGI program
  Thanks for visiting!
  Connection closed by foreign host.
```

Tiny Serving Dynamic Content

```
/* Return first part of HTTP response */
    sprintf(buf, "HTTP/1.0 200 OK\r\n");
    Rio_writen(fd, buf, strlen(buf));
    sprintf(buf, "Server: Tiny Web Server\r\n");
    Rio_writen(fd, buf, strlen(buf));

if (Fork() == 0) { /* child */
        /* Real server would set all CGI vars here */
        setenv("QUERY_STRING", cgiargs, 1);
        Dup2(fd, STDOUT_FILENO); /* Redirect stdout to client */
        Execve(filename, emptylist, environ);/* Run CGI prog */
}
Wait(NULL); /* Parent waits for and reaps child */
```

- Fork child to execute CGI program
- Change stdout to be connection to client
- Execute CGI program with execve

Data Transfer Mechanisms

Standard

- Specify total length with content-length
- Requires that program buffer entire message

Chunked

- Break into blocks
- Prefix each block with number of bytes (Hex coded)

Chunked Encoding Example

```
HTTP/1.1 200 OK\n
Date: Sun, 31 Oct 2010 20:47:48 GMT\n
Server: Apache/1.3.41 (Unix)\n
Keep-Alive: timeout=15, max=100\n
Connection: Keep-Alive\n
Transfer-Encoding: chunked\n
Content-Type: text/html\n
d75\r\n
        First Chunk: 0xd75 = 3445 bytes
<h+m1>
<head>
.....<du/style/calendar.css" rel="stylesheet"</li>
type="text/css">
</head>
<body id="calendar body">
<div id='calendar'>
cellspacing='1' id='cal'>
</body>
</html>
        Second Chunk: 0 bytes (indicates last chunk)
0\r\n
```

For More Information

Study the Tiny Web server described in your text

- Tiny is a sequential Web server.
- Serves static and dynamic content to real browsers.
 - text files, HTML files, GIF and JPEG images.
- 220 lines of commented C code.
- Also comes with an implementation of the CGI script for the add.com addition portal.

See the HTTP/1.1 standard:

http://www.w3.org/Protocols/rfc2616/rfc2616.html

URLs

- Each file managed by a server has a unique name called a URL (Universal Resource Locator)
- URLs for static content:
 - http://www.cs.cmu.edu:80/index.html
 - http://www.cs.cmu.edu/index.html
 - http://www.cs.cmu.edu
 - Identifies a file called index.html, managed by a Web server at www.cs.cmu.edu that is listening on port 80
- URLs for dynamic content:
 - http://www.cs.cmu.edu:8000/cgi-bin/proc?15000&213
 - Identifies an executable file called proc, managed by a Web server at www.cs.cmu.edu that is listening on port 8000, that should be called with two argument strings: 15000 and 213
