# Virtual Memory Abstraction

## ■ Programs refer to virtual memory addresses

- `movl (%ecx),%eax`
- Conceptually very large array of bytes
- Each byte has its own address
- Actually implemented with hierarchy of different memory types
- System provides address space private to particular “process”

## ■ Allocation: Compiler and run-time system

- Where different program objects should be stored
- All allocation within single virtual address space

## ■ But why virtual memory?

## ■ Why not physical memory?

# Problem 1: How Does Everything Fit?

64-bit addresses:  
16 Exabyte

Physical main memory:  
Few Gigabytes

And there are many processes ....

# Problem 2: Memory Management

Process 1  
Process 2  
Process 3  
...  
Process n

**X**

stack  
heap  
.text  
.data  
...

What goes  
where?

Physical main memory

## Problem 3: How To Protect

## Problem 4: How To Share?

# Solution: Level Of Indirection

- Each process gets its own private memory space
- Solves the previous problems

# One simple trick solves all of these problems

- **Each process gets its own private image of memory**
  - appears to be a full-sized private memory range
- **This fixes “how to choose” and “others shouldn’t mess w/ yours”**
  - in addition to “making everything fit”
- **Implementation: translate addresses transparently**
  - add a mapping function
    - to map private (i.e. “virtual”) addresses to physical addresses
  - do the mapping on every load or store
- **This mapping trick is the heart of *virtual memory***

# Address Spaces

- **Linear address space:** Ordered set of contiguous non-negative integer addresses:

$\{0, 1, 2, 3 \dots \}$

- **Virtual address space:** Set of  $N = 2^n$  virtual addresses

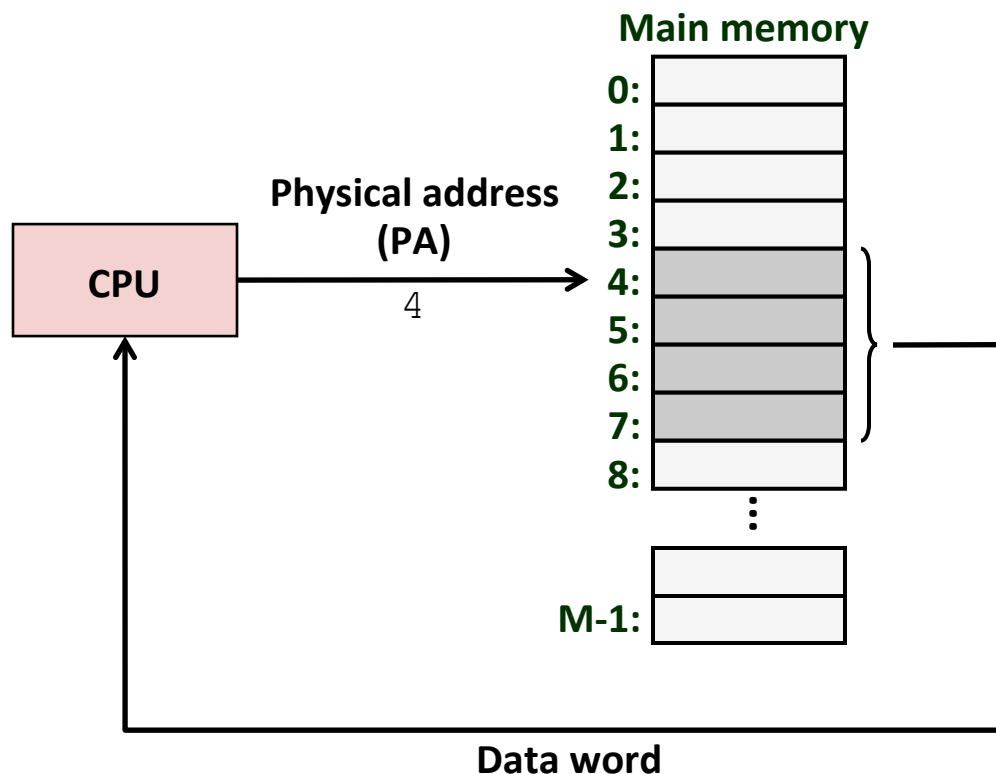

$\{0, 1, 2, 3, \dots, N-1\}$

- **Physical address space:** Set of  $M = 2^m$  physical addresses

$\{0, 1, 2, 3, \dots, M-1\}$

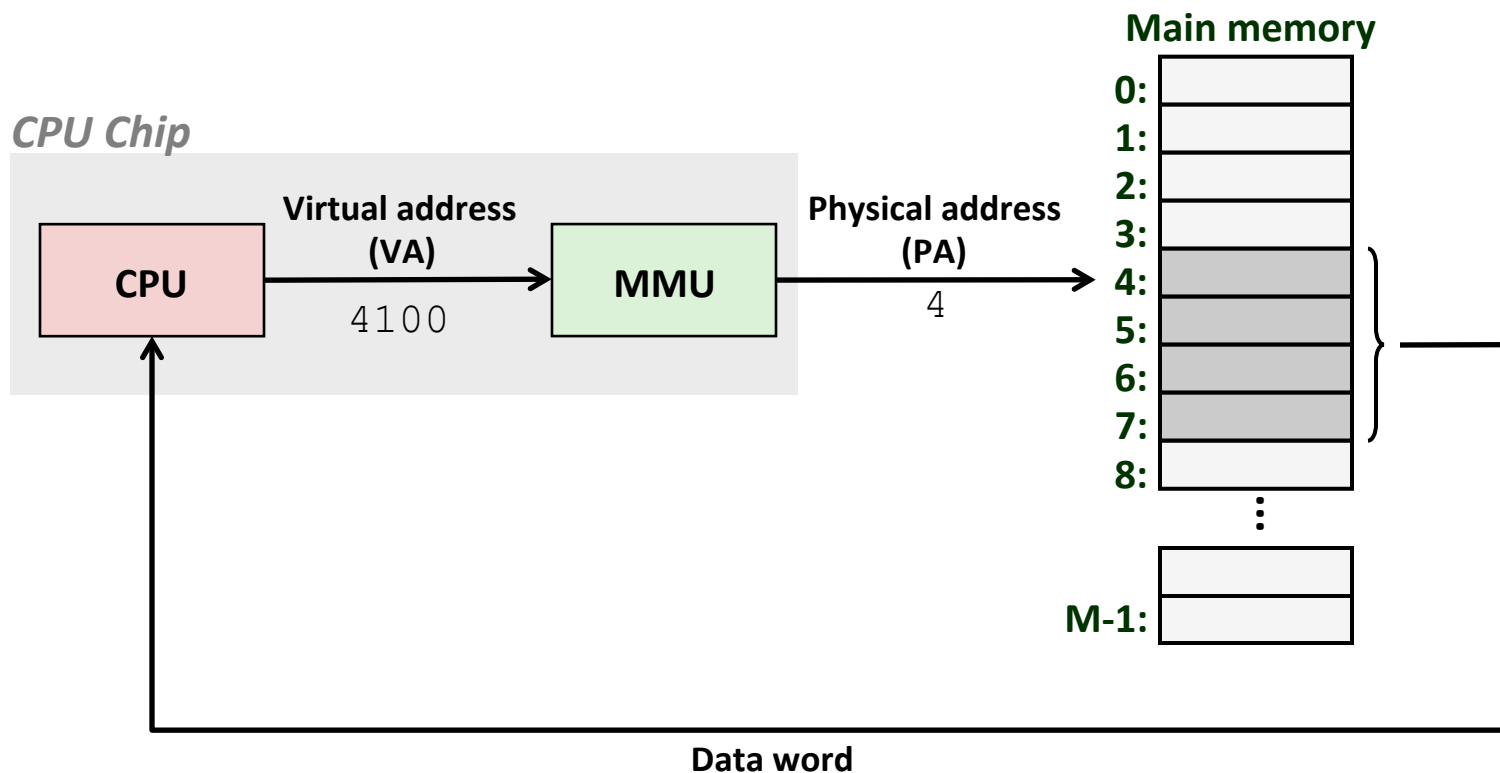

- **Clean distinction between data (bytes) and their attributes (addresses)**
- **Each datum can now have multiple addresses**
- **Every byte in main memory:  
one physical address, one (or more) virtual addresses**

# A System Using Physical Addressing

- Used in “simple” systems like embedded microcontrollers in devices like cars, elevators, and digital picture frames

# A System Using Virtual Addressing

- Used in all modern servers, desktops, and laptops
- One of the great ideas in computer science

# Why Virtual Memory (summary)?

- **Uses main memory (RAM) efficiently**
  - Use DRAM as a cache for the parts of a virtual address space
- **Simplifies memory management**
  - Each process gets the same uniform linear address space
- **Isolates address spaces**
  - One process can't interfere with another's memory
  - User program cannot access privileged kernel information

# (1) VM as a Tool for Caching

- **Virtual memory** is an array of  $N$  contiguous bytes stored on disk.
- The contents of the array on disk are cached in **physical memory (DRAM cache)**
  - These cache blocks are called *pages* (size is  $P = 2^p$  bytes)

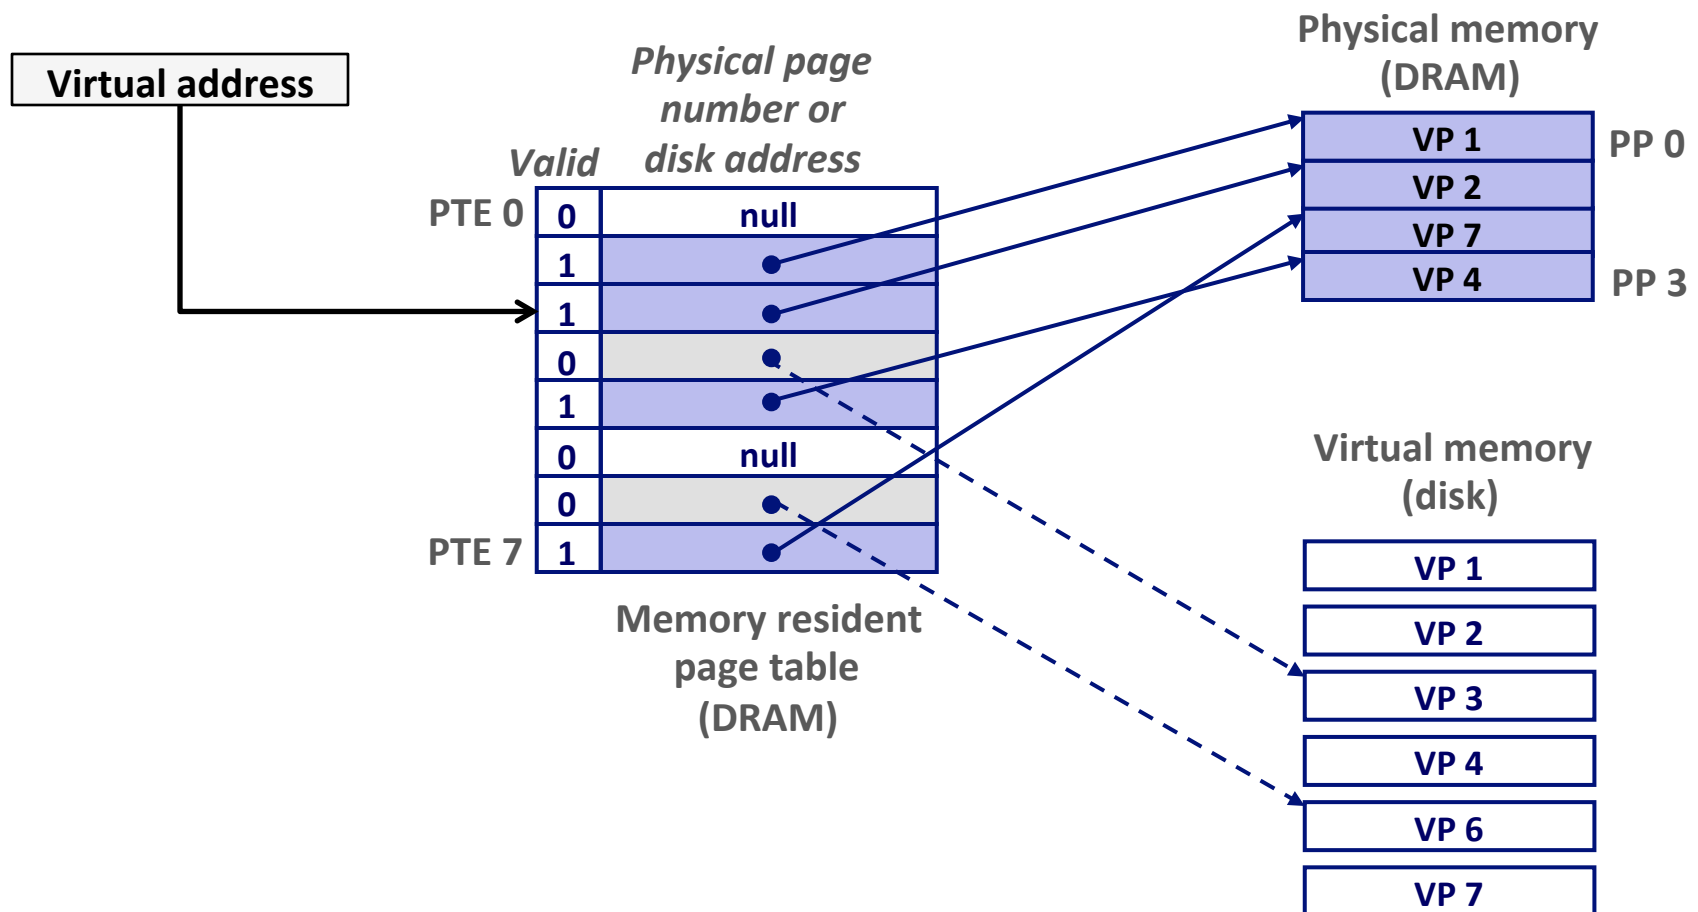

# Enabling data structure: Page Table

- A *page table* is an array of page table entries (PTEs) that maps virtual pages to physical pages.
  - Per-process kernel data structure in DRAM

# Page Hit

- **Page hit:** reference to VM word that is in physical memory (DRAM cache hit)

# Page Fault

- **Page fault:** reference to VM word that is not in physical memory (DRAM cache miss)

# Handling Page Fault

- Page miss causes page fault (an exception)

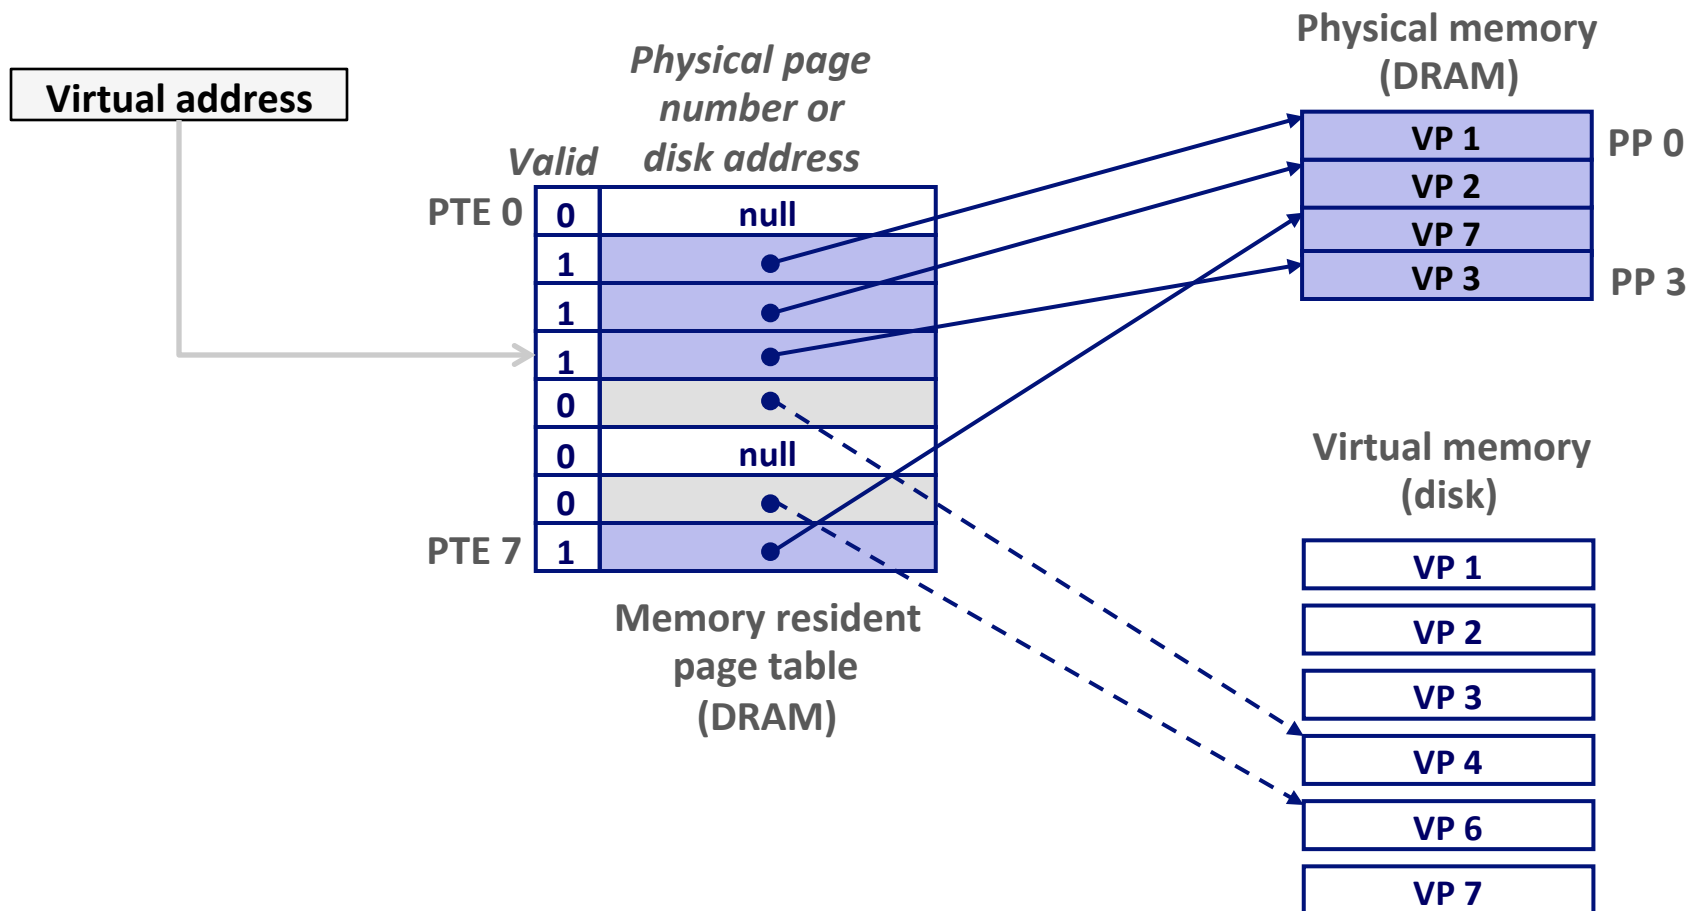

# Handling Page Fault

- Page miss causes page fault (an exception)
- Page fault handler selects a victim to be evicted (here VP 4)

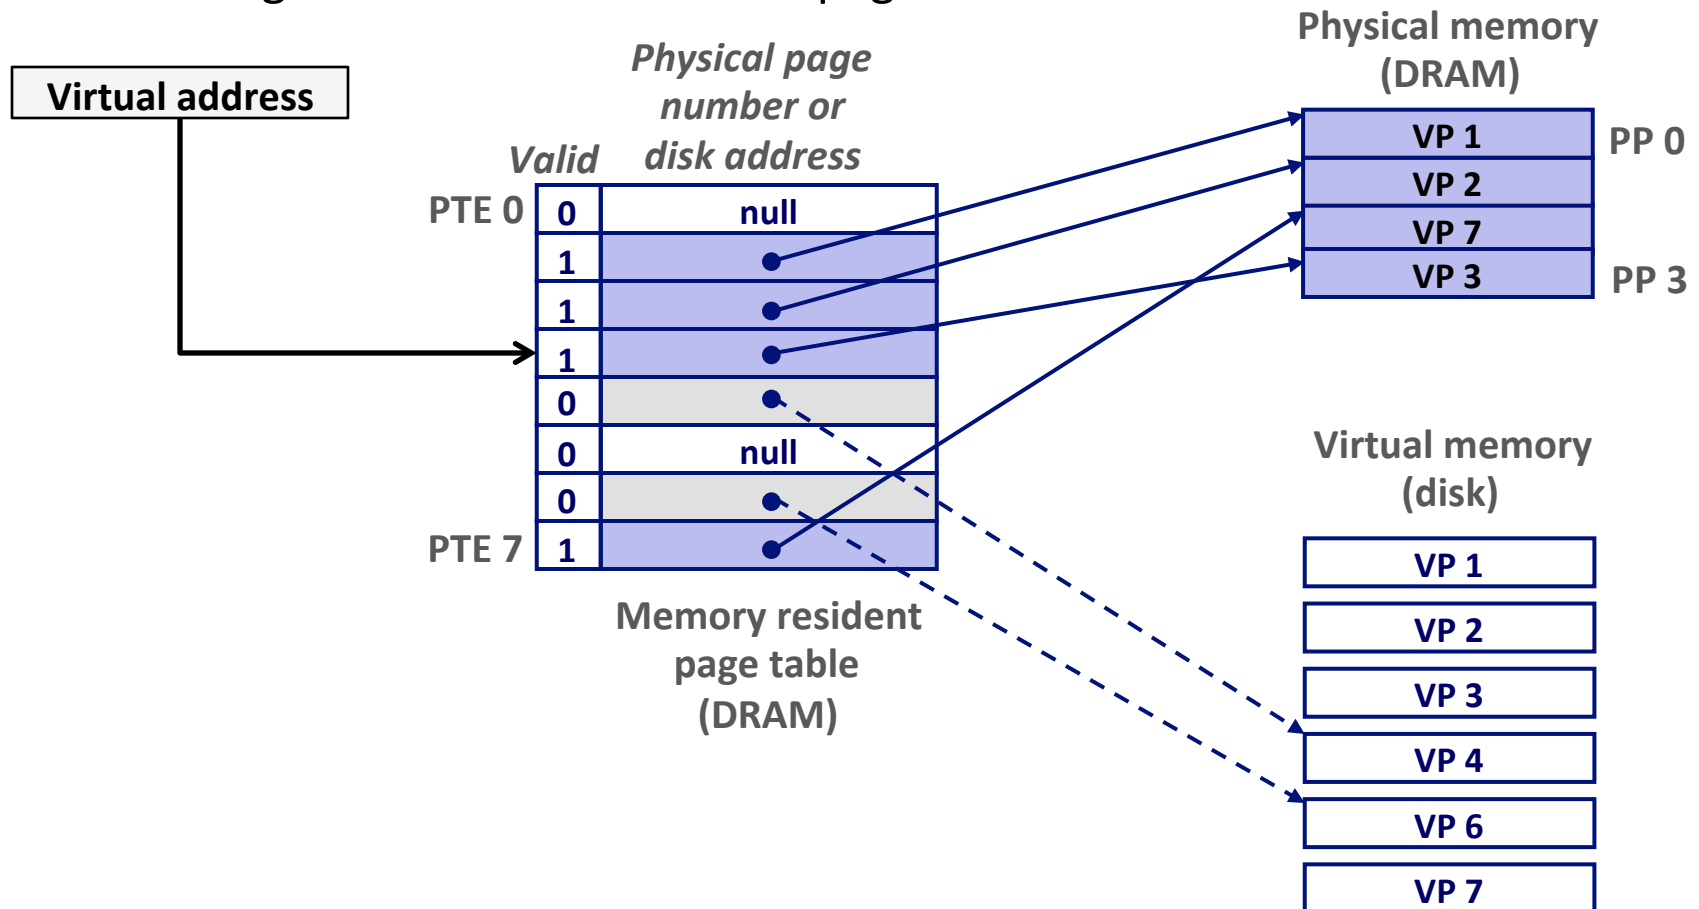

# Handling Page Fault

- Page miss causes page fault (an exception)
- Page fault handler selects a victim to be evicted (here VP 4)

# Handling Page Fault

- Page miss causes page fault (an exception)
- Page fault handler selects a victim to be evicted (here VP 4)
- Offending instruction is restarted: page hit!

# Locality to the Rescue Again!

- Virtual memory works because of locality
- At any point in time, programs tend to access a set of active virtual pages called the *working set*
  - Programs with better temporal locality will have smaller working sets
- If (working set size < main memory size)
  - Good performance for one process after compulsory misses
- If ( SUM(working set sizes) > main memory size )
  - *Thrashing*: Performance meltdown where pages are moved (copied) in and out continuously

## (2) VM as a Tool for Memory Management

- **Key idea: each process has its own virtual address space**
  - It can view memory as a simple linear array
  - Mapping function scatters addresses through physical memory
    - Well chosen mappings simplify memory allocation and management

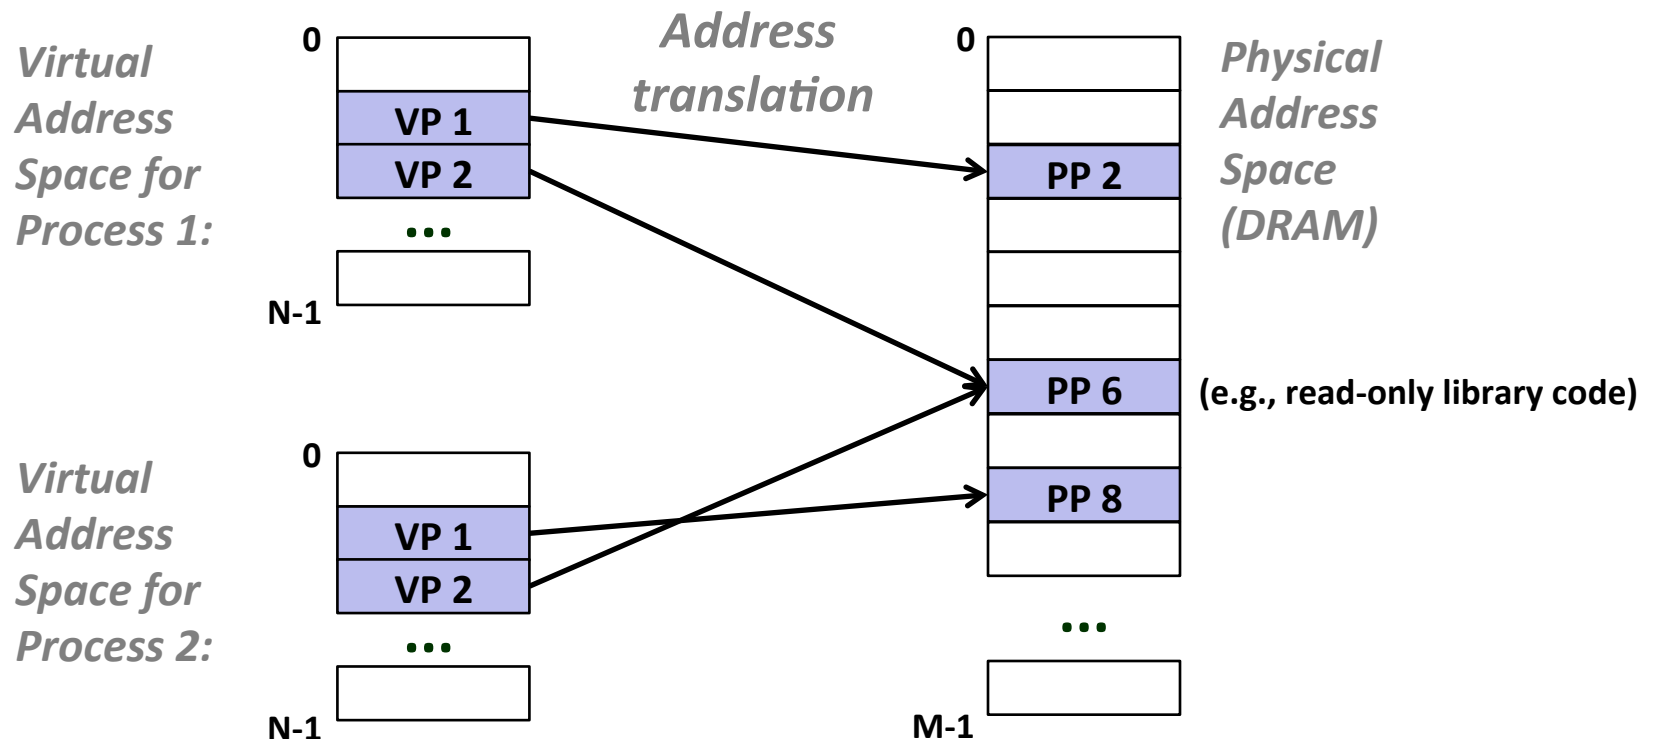

# Simplifying allocation and sharing

## ■ Memory allocation

- Each virtual page can be mapped to any physical page
- A virtual page can be stored in different physical pages at different times

## ■ Sharing code and data among processes

- Map multiple virtual pages to the same physical page (here: PP 6)

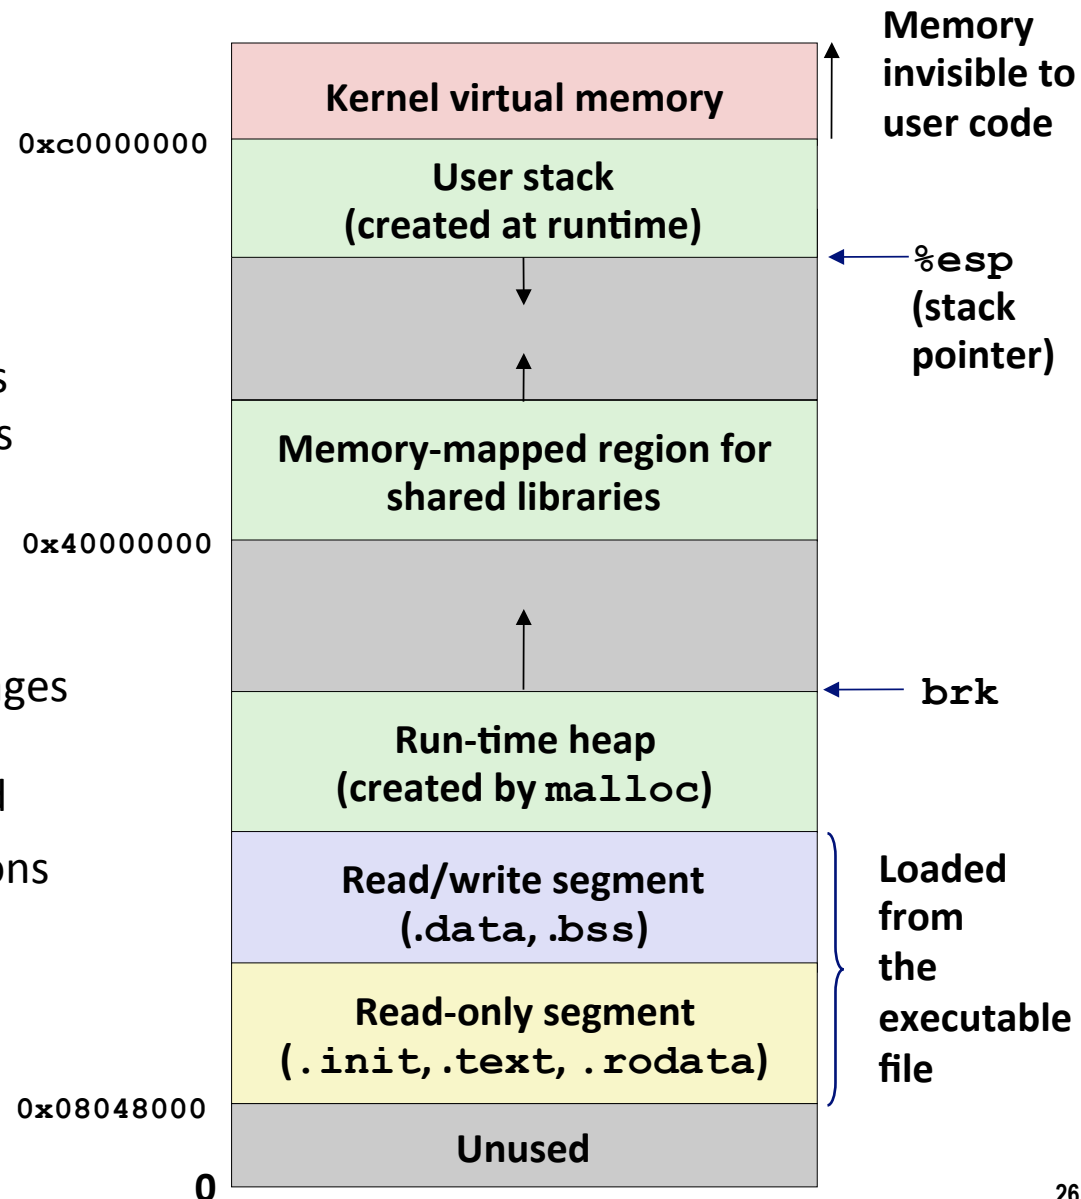

# Simplifying Linking and Loading

## ■ Linking

- Each program has similar virtual address space
- Code, stack, and shared libraries always start at the same address

## ■ Loading

- `execve()` allocates virtual pages for `.text` and `.data` sections = creates PTEs marked as invalid
- The `.text` and `.data` sections are copied, page by page, on demand by the virtual memory system

# VM as a Tool for Memory Protection

- Extend PTEs with permission bits
- Page fault handler checks these before remapping
  - If violated, send process SIGSEGV (segmentation fault)

# VM Address Translation

## ■ Virtual Address Space

- $V = \{0, 1, \dots, N-1\}$

## ■ Physical Address Space

- $P = \{0, 1, \dots, M-1\}$

## ■ Address Translation

- $MAP: V \rightarrow P \cup \{\emptyset\}$

- For virtual address  $a$ :

- $MAP(a) = a'$  if data at virtual address  $a$  is at physical address  $a'$  in  $P$
- $MAP(a) = \emptyset$  if data at virtual address  $a$  is not in physical memory
  - Either invalid or stored on disk

# Summary of Address Translation Symbols

## ■ Basic Parameters

- $N = 2^n$  : Number of addresses in virtual address space
- $M = 2^m$  : Number of addresses in physical address space
- $P = 2^p$  : Page size (bytes)

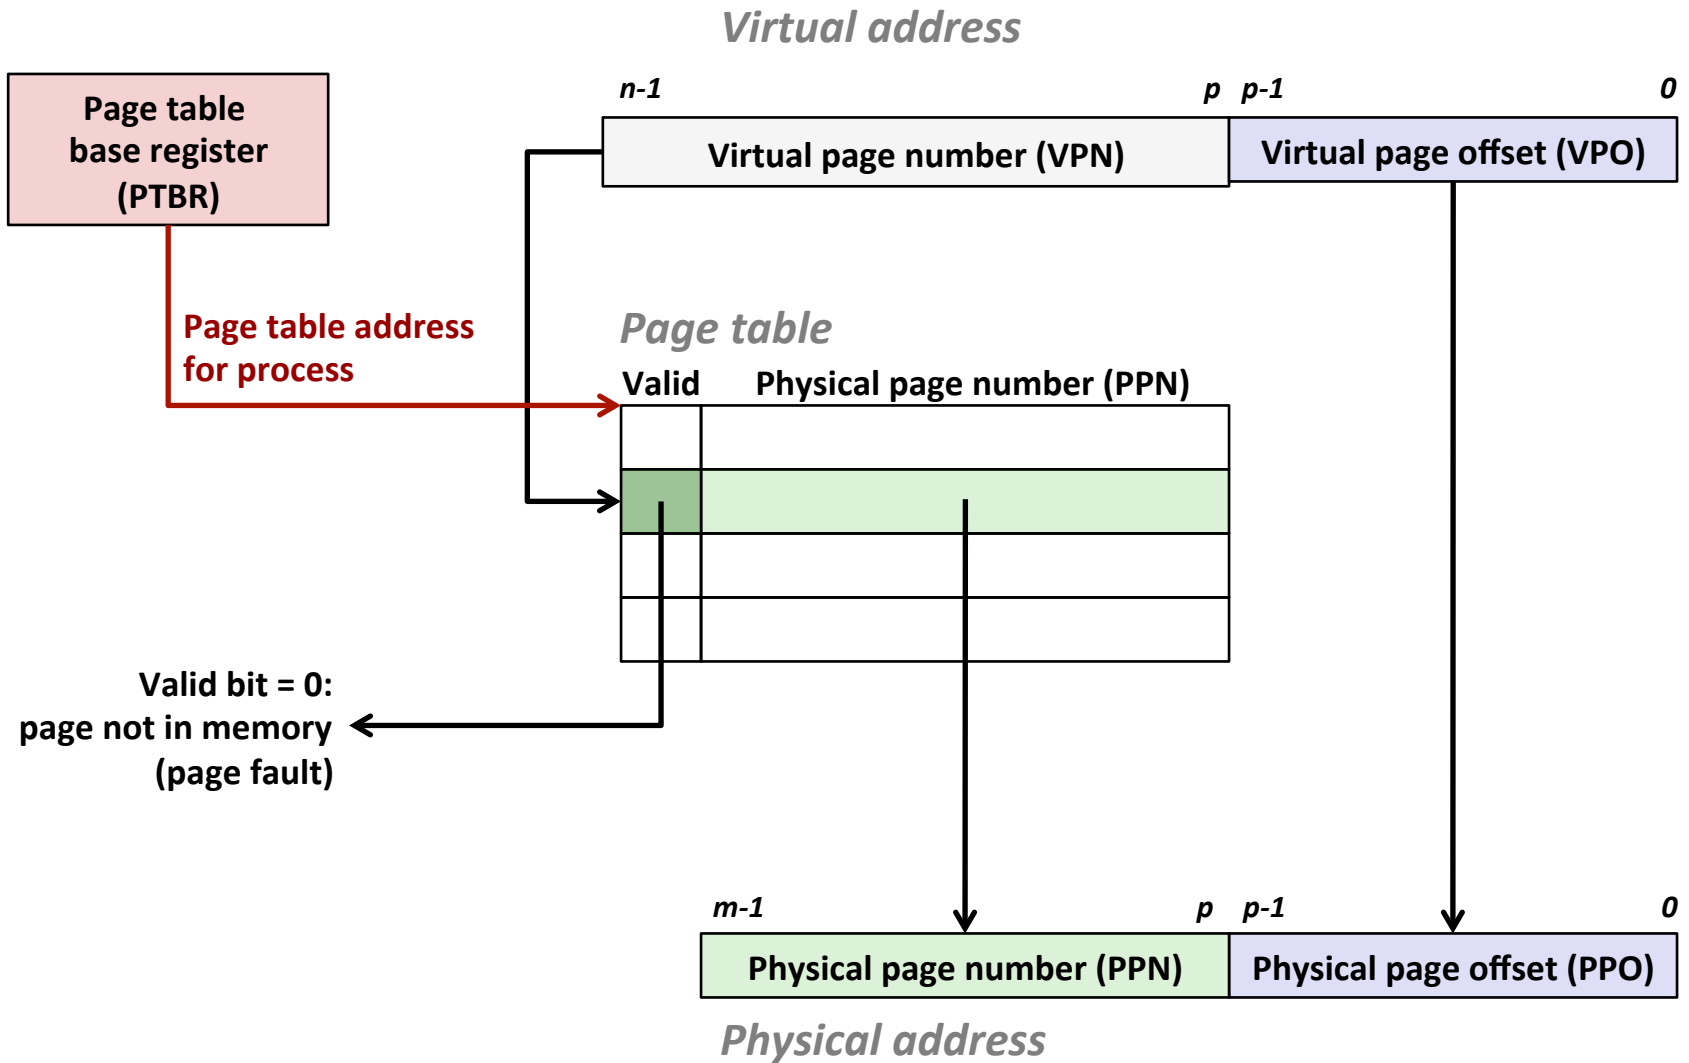

## ■ Components of the virtual address (VA)

- **VPO**: Virtual page offset
- **VPN**: Virtual page number
- **TLBI**: TLB index
- **TLBT**: TLB tag

## ■ Components of the physical address (PA)

- **PPO**: Physical page offset (same as VPO)
- **PPN**: Physical page number
- **CO**: Byte offset within cache line
- **CI**: Cache index
- **CT**: Cache tag

# Address Translation With a Page Table

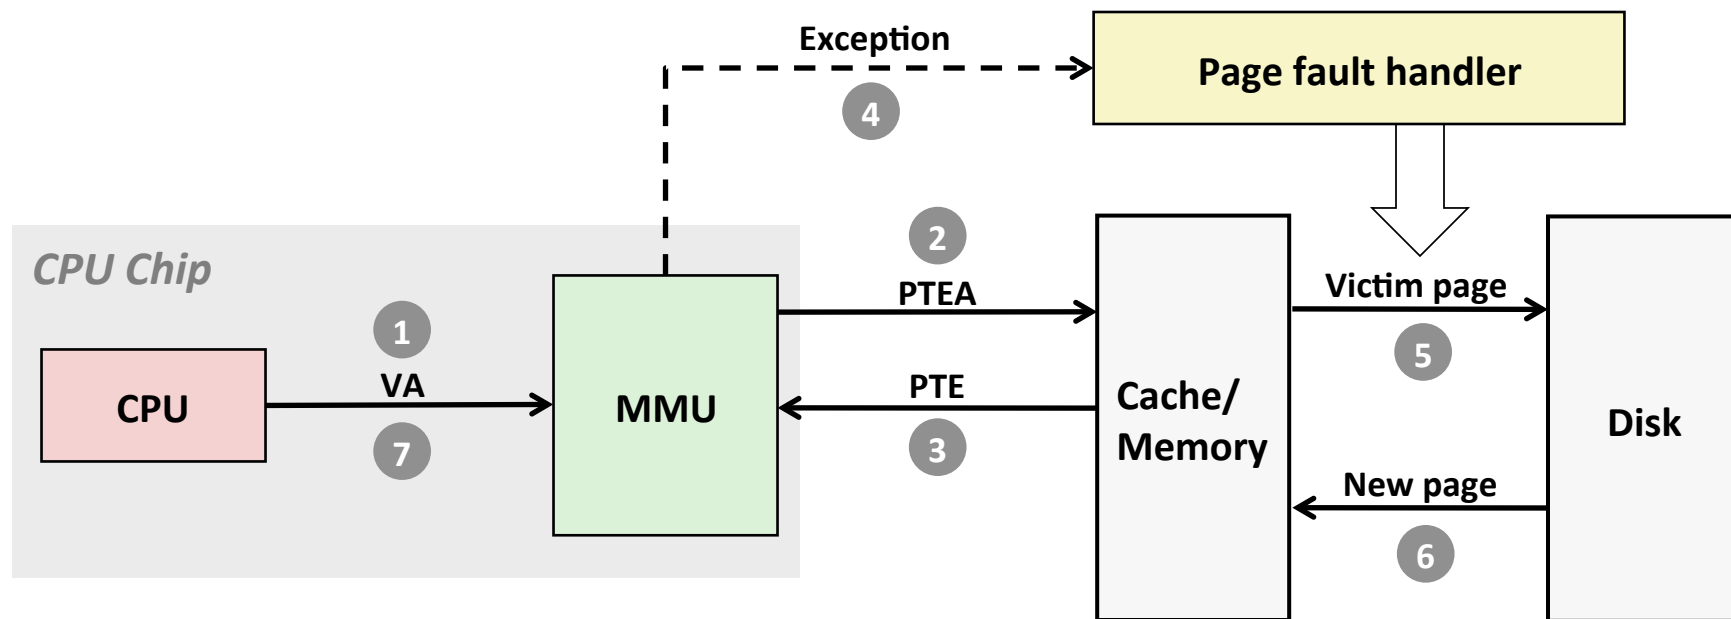

# Address Translation: Page Hit

- 1) Processor sends virtual address to MMU
- 2-3) MMU fetches PTE from page table in memory
- 4) MMU sends physical address to cache/memory
- 5) Cache/memory sends data word to processor

# Address Translation: Page Fault

- 1) Processor sends virtual address to MMU
- 2-3) MMU fetches PTE from page table in memory
- 4) Valid bit is zero, so MMU triggers page fault exception
- 5) Handler identifies victim (and, if dirty, pages it out to disk)
- 6) Handler pages in new page and updates PTE in memory
- 7) Handler returns to original process, restarting faulting instruction

# Views of virtual memory

## ■ Programmer's view of virtual memory

- Each process has its own private linear address space
- Cannot be corrupted by other processes

## ■ System view of virtual memory

- Uses memory efficiently by caching virtual memory pages
  - Efficient only because of locality
- Simplifies memory management and programming
- Simplifies protection by providing a convenient interpositioning point to check permissions

# Integrating VM and Cache

*VA: virtual address, PA: physical address, PTE: page table entry, PTEA = PTE address*

# Speeding up Translation with a TLB

- **Page table entries (PTEs) are cached in L1 like any other memory word**
  - PTEs may be evicted by other data references
  - PTE hit still requires a small L1 delay
- **Solution: *Translation Lookaside Buffer* (TLB)**
  - Small hardware cache in MMU
  - Maps virtual page numbers to physical page numbers
  - Contains complete page table entries for small number of pages

# TLB Hit

**A TLB hit eliminates a memory access**

# TLB Miss

**A TLB miss incurs an additional memory access (the PTE)**

Fortunately, TLB misses are rare. Why?

# Conclusions

## (1) VM allows efficient use of limited main memory (RAM)

- Use RAM as a cache for the parts of a virtual address space
  - some non-cached parts stored on disk
  - some (unallocated) non-cached parts stored nowhere
- Keep only active areas of virtual address space in memory
  - transfer data back and forth as needed

## (2) VM simplifies memory management for programmers

- Each process gets a full, private linear address space

## (3) VM isolates address spaces

- One process can't interfere with another's memory
  - because they operate in different address spaces
- User process cannot access privileged information
  - different sections of address spaces have different permissions
