

# **Machine learning: a very quick introduction**

# Why is learning important?

- Many AI techniques require that **we know how the world works**
  - Rules of puzzles
  - Rules of games
  - Logic
  - Planning
  - Probabilistic reasoning
  - Decision making
- At that point “just” need to solve/optimize
- In the real world this information is often not immediately available
- Also, some things are hard to formalize
- AI needs to be able to **learn from experience**
- (Sometimes learning is a good way to optimize too!)

# Different kinds of learning...

- **Supervised learning:**
  - Someone gives us examples and the right answer (*label*) for those examples
  - We have to predict the right answer for unseen examples
- **Unsupervised learning:**
  - We see examples but get no feedback (no labels)
  - We need to find patterns in the data
- **Semi-supervised learning:**
  - Small amount of labeled data, large amount of unlabeled data
- **Reinforcement learning:**
  - We take actions and get rewards
  - Have to learn how to get high rewards

# Example of supervised learning: classification

- We lend money to people
- We have to predict whether they will pay us back or not
- People have various (say, binary) features:
  - do we know their Address? do they have a Criminal record? high Income? Educated? Old? Unemployed?
- We see examples: (Y = paid back, N = not)
  - +a, -c, +i, +e, +o, +u: Y
  - a, +c, -i, +e, -o, -u: N
  - +a, -c, +i, -e, -o, -u: Y
  - a, -c, +i, +e, -o, -u: Y
  - a, +c, +i, -e, -o, -u: N
  - a, -c, +i, -e, -o, +u: Y
  - +a, -c, -i, -e, +o, -u: N
  - +a, +c, +i, -e, +o, -u: N
- Next person is +a, -c, +i, -e, +o, -u. Will we get paid back?

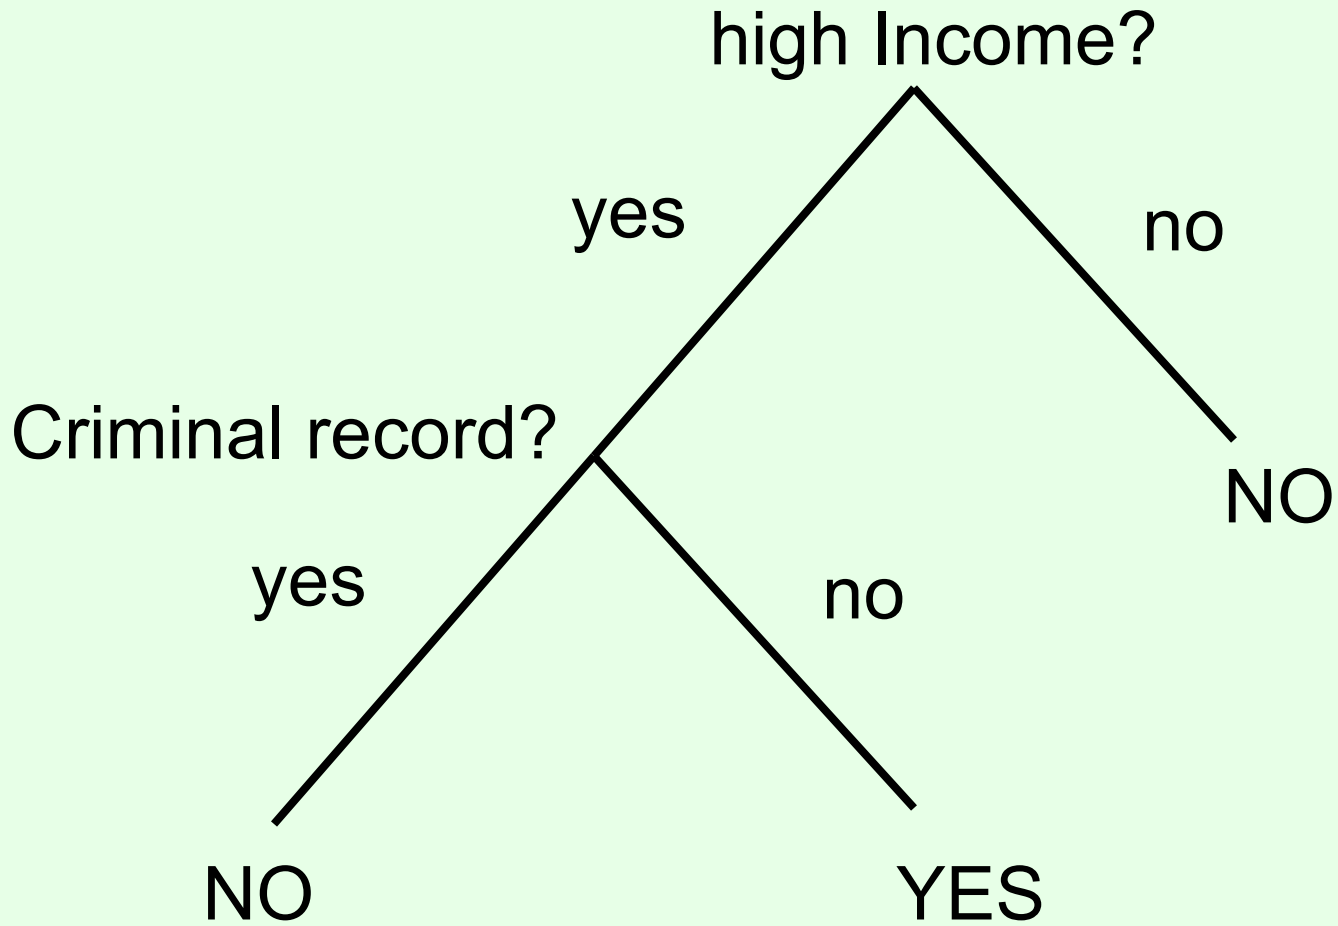

# Classification...

- We want some **hypothesis**  $h$  that predicts whether we will be paid back
  - +a, -c, +i, +e, +o, +u: Y
  - a, +c, -i, +e, -o, -u: N
  - +a, -c, +i, -e, -o, -u: Y
  - a, -c, +i, +e, -o, -u: Y
  - a, +c, +i, -e, -o, -u: N
  - a, -c, +i, -e, -o, +u: Y
  - +a, -c, -i, -e, +o, -u: N
  - +a, +c, +i, -e, +o, -u: N
- Lots of possible hypotheses: will be paid back if...
  - Income is high (*wrong on 2 occasions in training data*)
  - Income is high and no Criminal record (*always right in training data*)
  - (Address is known AND ((NOT Old) OR Unemployed)) OR ((NOT Address is known) AND (NOT Criminal Record)) (*always right in training data*)
- Which one seems best? Anything better?

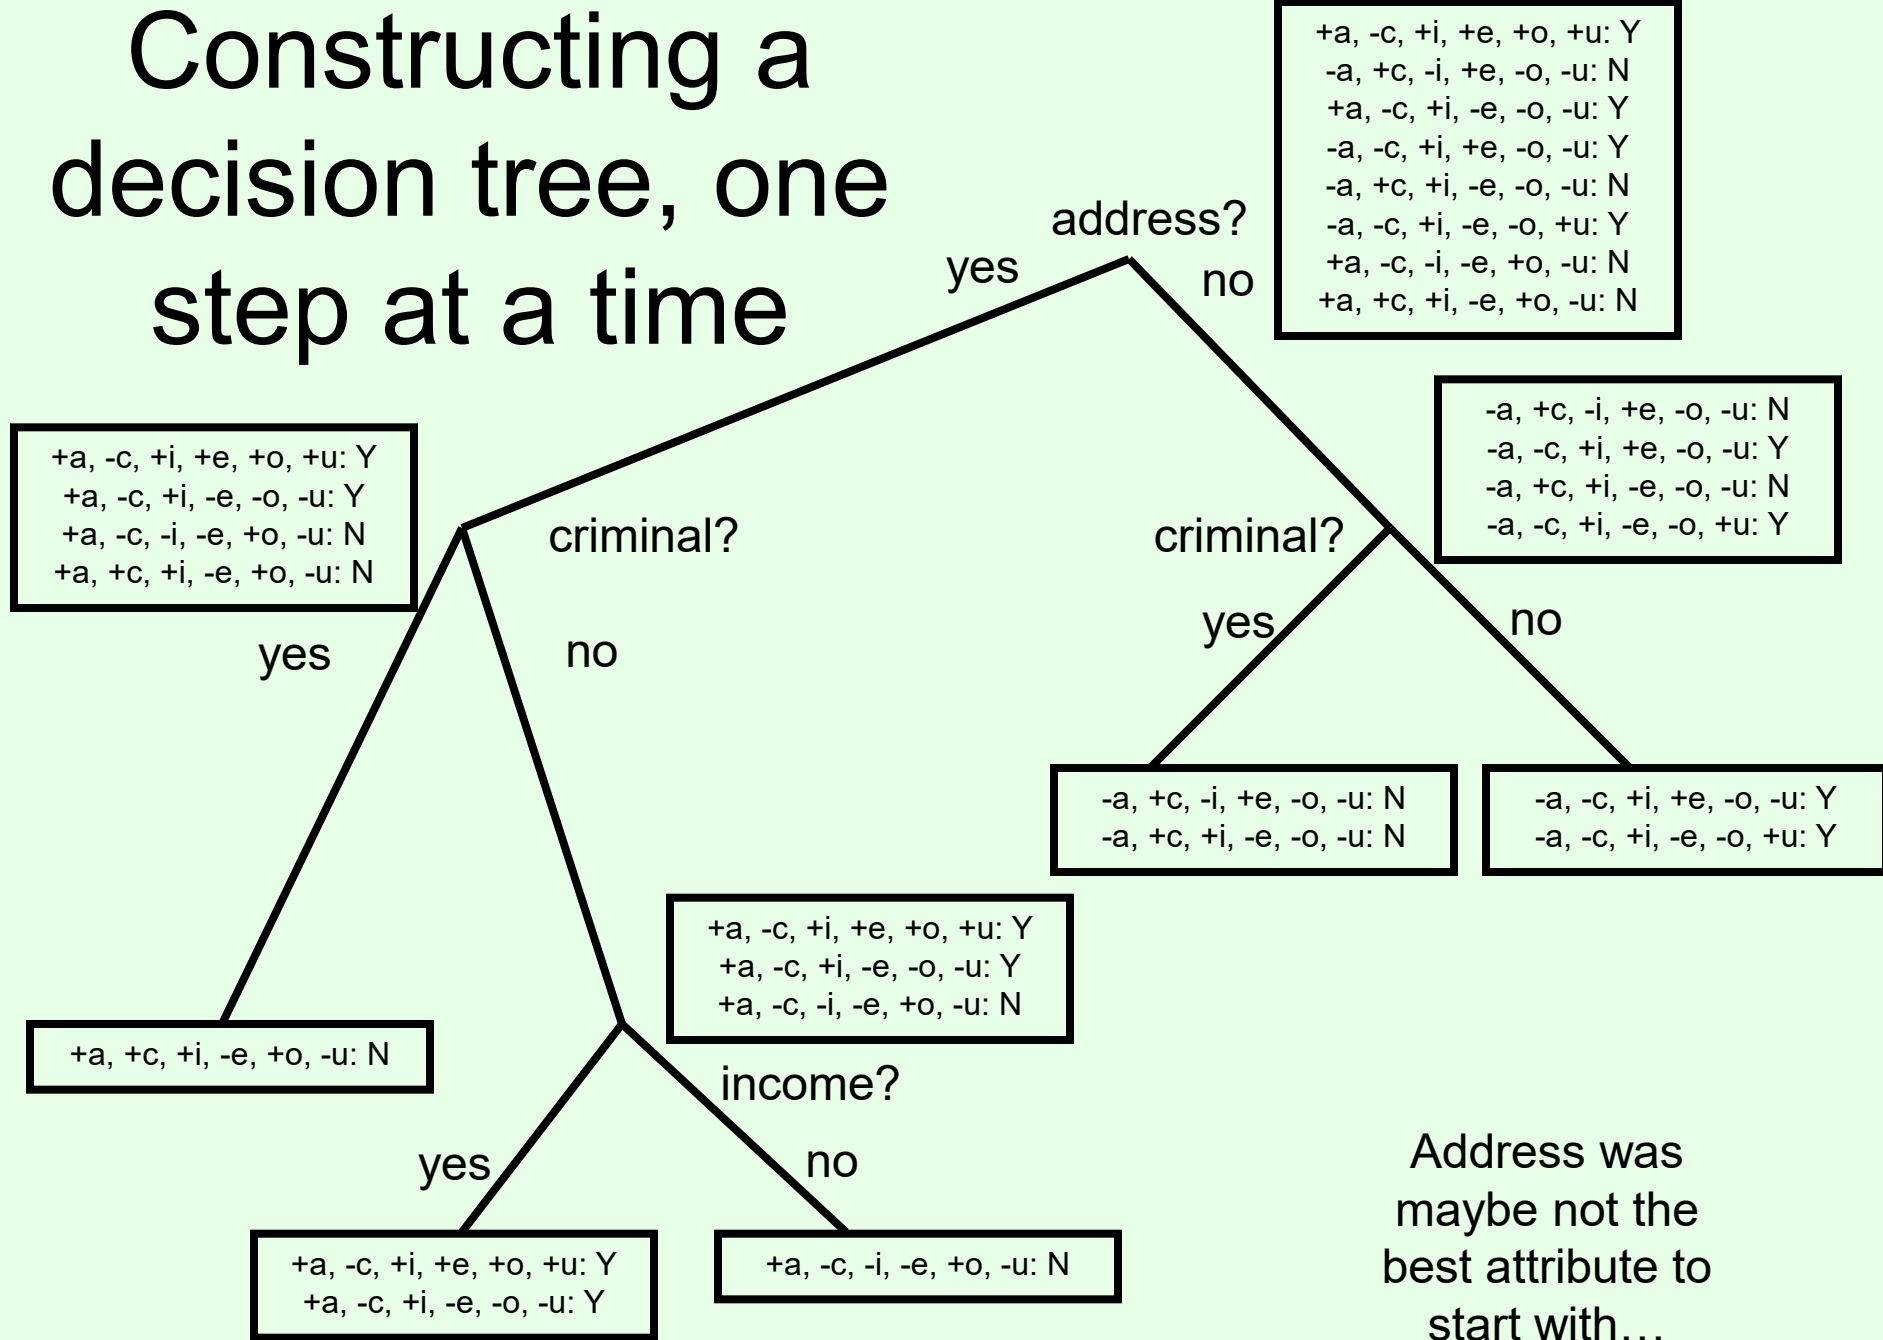

# Occam's Razor

- Occam's razor: *simpler hypotheses tend to generalize to future data better*
- Intuition: given limited training data,
  - it is likely that there is some **complicated** hypothesis that is not actually good but that happens to perform well on the training data
  - it is less likely that there is a **simple** hypothesis that is not actually good but that happens to perform well on the training data
    - There are fewer simple hypotheses
- **Computational learning theory** studies this in much more depth

# Decision trees

# Constructing a decision tree, one step at a time

+a, -c, +i, +e, +o, +u: Y  
 -a, +c, -i, +e, -o, -u: N  
 +a, -c, +i, -e, -o, -u: Y  
 -a, -c, +i, +e, -o, -u: Y  
 -a, +c, +i, -e, -o, -u: N  
 -a, -c, +i, -e, -o, +u: Y  
 +a, -c, -i, -e, +o, -u: N  
 +a, +c, +i, -e, +o, -u: N

-a, +c, -i, +e, -o, -u: N  
 -a, -c, +i, +e, -o, -u: Y  
 -a, +c, +i, -e, -o, -u: N  
 -a, -c, +i, -e, -o, +u: Y

+a, -c, +i, +e, +o, +u: Y  
 +a, -c, +i, -e, -o, -u: Y  
 +a, -c, -i, -e, +o, -u: N  
 +a, +c, +i, -e, +o, -u: N

-a, +c, -i, +e, -o, -u: N  
 -a, +c, +i, -e, -o, -u: N

-a, -c, +i, +e, -o, -u: Y  
 -a, -c, +i, -e, -o, +u: Y

+a, -c, +i, +e, +o, +u: Y  
 +a, -c, +i, -e, -o, -u: Y  
 +a, -c, -i, -e, +o, -u: N

+a, +c, +i, -e, +o, -u: N

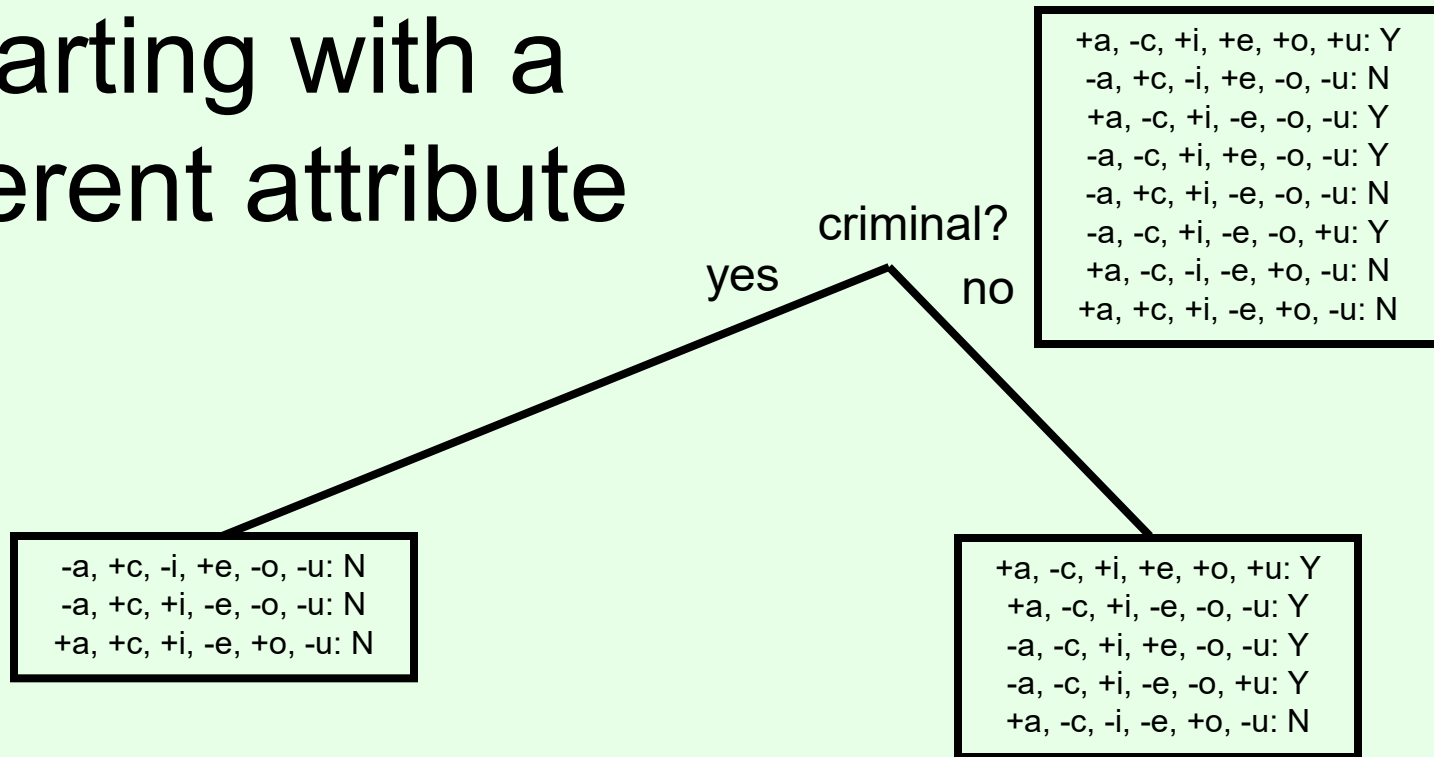

+a, -c, +i, +e, +o, +u: Y  
 +a, -c, +i, -e, -o, -u: Y

+a, -c, -i, -e, +o, -u: N

Address was maybe not the best attribute to start with...

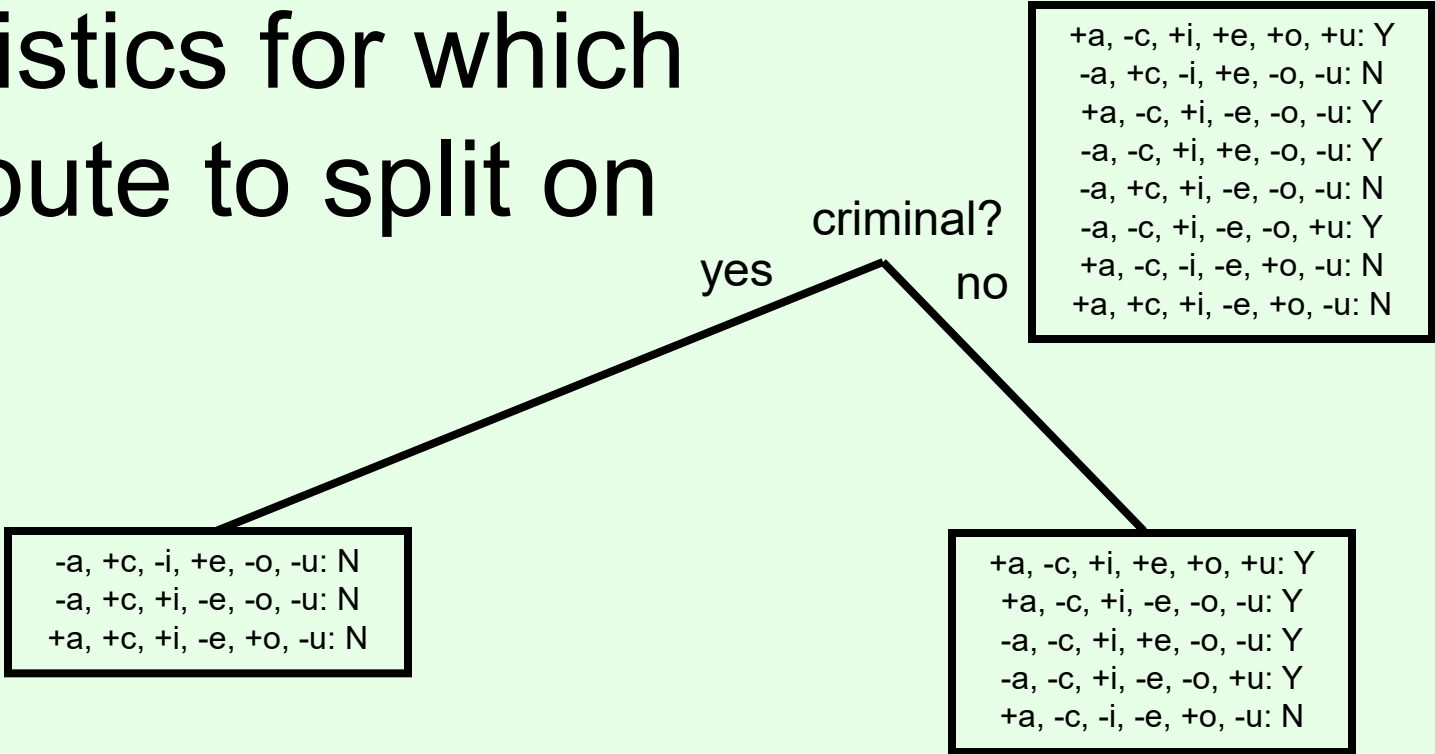

# Starting with a different attribute

- Seems like a much better starting point than address
  - Each node almost completely uniform
  - Almost completely predicts whether we will be paid back

# Heuristics for which attribute to split on

- Can you think of a good heuristic?
- Can you think of a perfect heuristic?

# An example

+a, +b, +c: Y

+a, +b, -c: Y

+a, -b, +c: N

+a, -b, -c: N

-a, +b, +c: N

-a, +b, -c: N

-a, -b, +c: Y

-a, -b, +c: Y

- What feature would you use if you can use only one?
- What if two?

# Different approach: nearest neighbor(s)

- Next person is -a, +c, -i, +e, -o, +u. Will we get paid back?
- Nearest neighbor: simply look at most similar example in the training data, see what happened there
  - +a, -c, +i, +e, +o, +u: Y (*distance 4*)
  - a, +c, -i, +e, -o, -u: N (*distance 1*)
  - +a, -c, +i, -e, -o, -u: Y (*distance 5*)
  - a, -c, +i, +e, -o, -u: Y (*distance 3*)
  - a, +c, +i, -e, -o, -u: N (*distance 3*)
  - a, -c, +i, -e, -o, +u: Y (*distance 3*)
  - +a, -c, -i, -e, +o, -u: N (*distance 5*)
  - +a, +c, +i, -e, +o, -u: N (*distance 5*)
- Nearest neighbor is second, so predict N
- k nearest neighbors: look at k nearest neighbors, take a vote
  - E.g., 5 nearest neighbors have 3 Ys, 2Ns, so predict Y

# Another approach: **perceptrons**

- Place a weight on every attribute, indicating how important that attribute is (and in which direction it affects things)
- E.g.,  $w_a = 1$ ,  $w_c = -5$ ,  $w_i = 4$ ,  $w_e = 1$ ,  $w_o = 0$ ,  $w_u = -1$ 
  - +a, -c, +i, +e, +o, +u: Y (score  $1+4+1+0-1 = 5$ )
  - a, +c, -i, +e, -o, -u: N (score  $-5+1=-4$ )
  - +a, -c, +i, -e, -o, -u: Y (score  $1+4=5$ )
  - a, -c, +i, +e, -o, -u: Y (score  $4+1=5$ )
  - a, +c, +i, -e, -o, -u: N (score  $-5+4=-1$ )
  - a, -c, +i, -e, -o, +u: Y (score  $4-1=3$ )
  - +a, -c, -i, -e, +o, -u: N (score  $1+0=1$ )
  - +a, +c, +i, -e, +o, -u: N (score  $1-5+4+0=0$ )
- Need to set some threshold above which we predict to be paid back (say, 2)
- May care about combinations of things (nonlinearity) – generalization: **neural networks**

# Features don't need to be binary

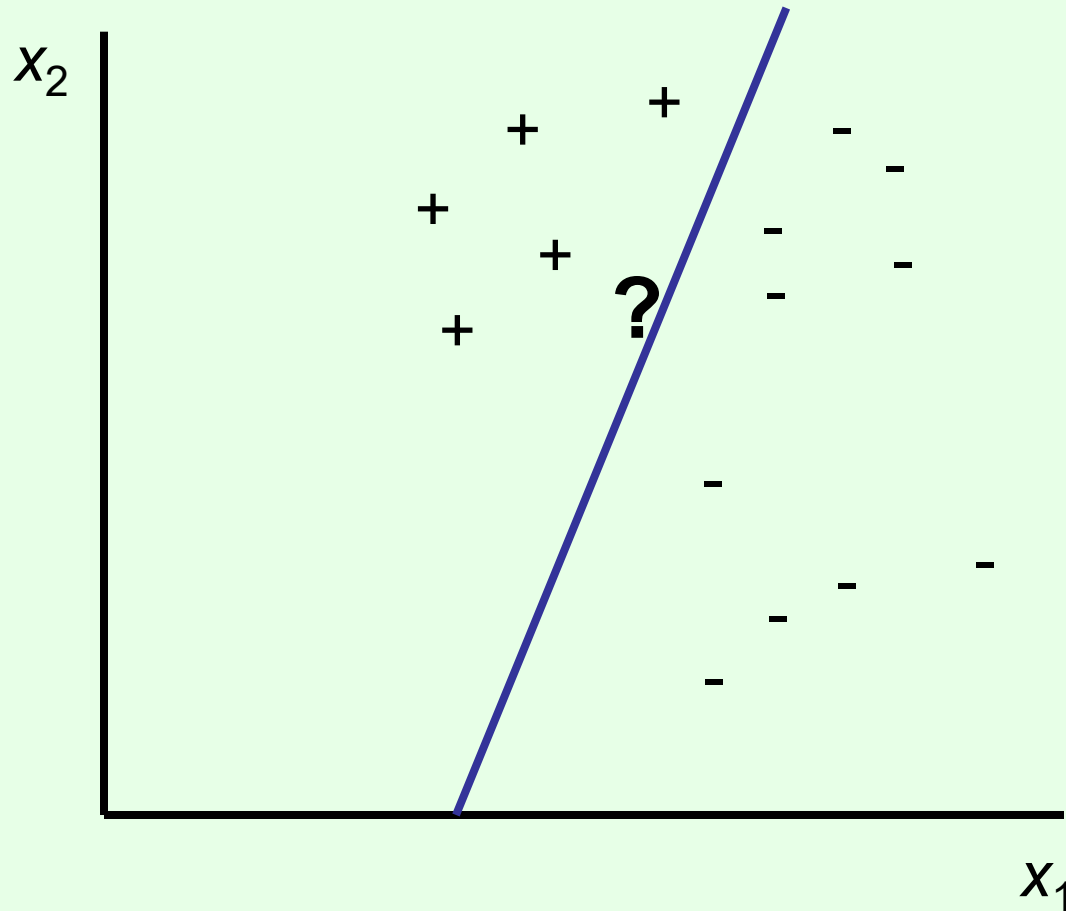

- Do you think the ? will pay back?

# Which classifier is better?

- Both blue and green classify points on the “southeast” side of them as positive

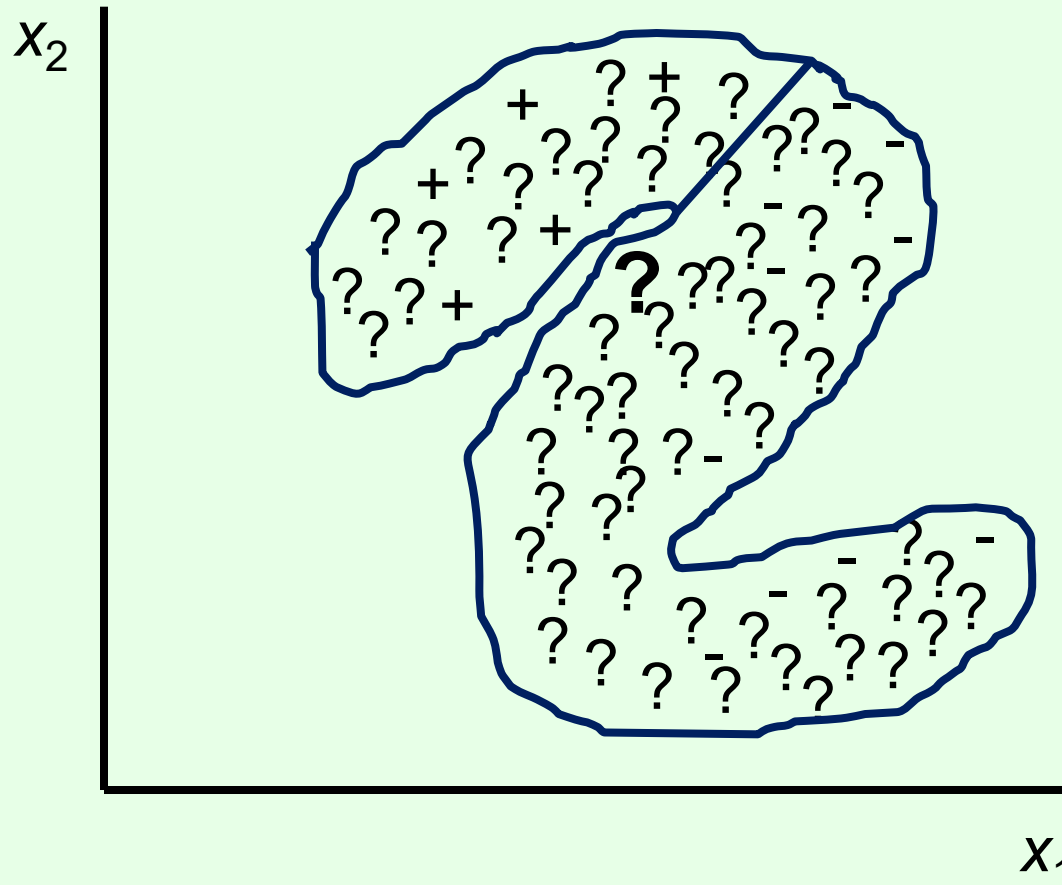

# Another example (say, novel scientific dataset)

- Do you think the big bold ? is positive?

# Another example (say, novel scientific dataset)

- Regular ?s are unlabeled
- Do you think the big bold ? is positive?

# Semi-supervised learning

- Sometimes there's a lot of unlabeled data that's easily available...
  - E.g., images
- ... while labeled data is harder to come by
  - E.g., have to pay someone to label those images
- Compare: recent shift to large **pretrained** / **foundation** models that are then **fine-tuned** for specific purposes

Step 1

**Collect demonstration data, and train a supervised policy.**

A prompt is sampled from our prompt dataset.

A labeler demonstrates the desired output behavior.

This data is used to fine-tune GPT-3 with supervised learning.

Step 2

**Collect comparison data, and train a reward model.**

A prompt and several model outputs are sampled.

A labeler ranks the outputs from best to worst.

This data is used to train our reward model.

Step 3

**Optimize a policy against the reward model using reinforcement learning.**

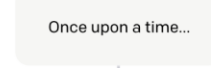

A new prompt is sampled from the dataset.

The policy generates an output.

The reward model calculates a reward for the output.

The reward is used to update the policy using PPO.

*“To train InstructGPT models, our core technique is reinforcement learning from human feedback (RLHF), a method we helped pioneer in our earlier alignment research. This technique uses human preferences as a reward signal to fine-tune our models, which is important as the safety and alignment problems we are aiming to solve are complex and subjective, and aren’t fully captured by simple automatic metrics.”*

# Self-supervised learning

- Wouldn't it be nice to do supervised learning without paying for labels?
- Common approach: remove something from the data, then try to predict the missing part
  - A word
  - Part of an image
  - The colors of an image
  - ...
- Allows training on very large datasets

# Reinforcement learning

- There are three routes you can take to work: A, B, C
- The times you took A, it took: 10, 60, 30 minutes
- The times you took B, it took: 32, 31, 34 minutes
- The time you took C, it took 50 minutes
- What should you do next?
- Exploration vs. exploitation tradeoff
  - **Exploration**: try to explore underexplored options
  - **Exploitation**: stick with options that look best now
- Reinforcement learning usually studied in MDPs
  - Take action, observe reward and new state

# Bayesian approach to learning

- Assume we have a **prior distribution** over the long-term behavior of A
  - With probability .6, A is a “fast route” which:
    - With prob. .25, takes 20 minutes
    - With prob. .5, takes 30 minutes
    - With prob. .25, takes 40 minutes
  - With probability .4, A is a “slow route” which:
    - With prob. .25, takes 30 minutes
    - With prob. .5, takes 40 minutes
    - With prob. .25, takes 50 minutes
- We travel on A once and see it takes 30 minutes
- $P(A \text{ is fast} \mid \text{observation}) = \frac{P(\text{observation} \mid A \text{ is fast}) \cdot P(A \text{ is fast})}{P(\text{observation})} = \frac{.5 \cdot .6}{.5 \cdot .6 + .25 \cdot .4} = \frac{.3}{.3 + .1} = .75$
- Convenient approach for decision theory, game theory

# Key assumption / issue: is the real world like the training data?

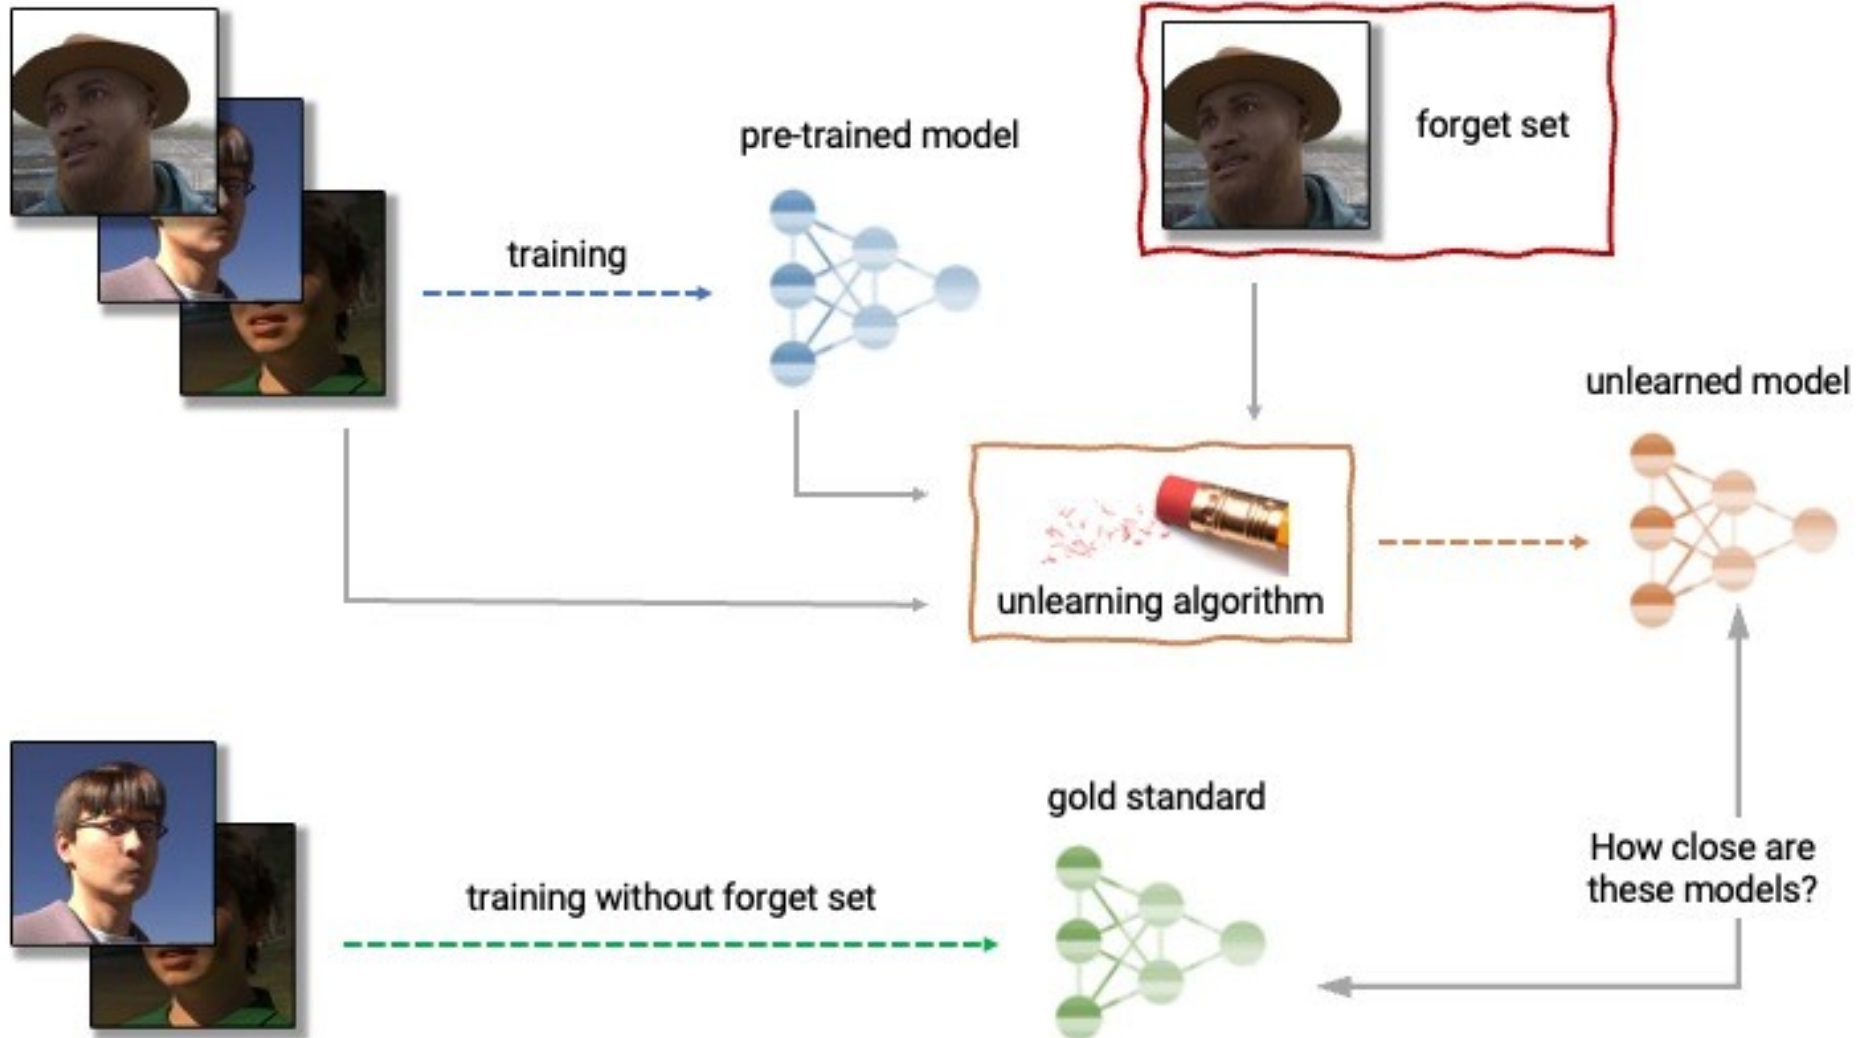

- Real world may not look like training data (out of distribution, OOD)
- Distribution changes over time
  - Use of “benefits” as a signal about the economy
- Tool applied in a different setting
  - E.g., medicine: different patient population, images taken in different way, ...
- People respond strategically to tool
  - E.g., resume screening
  - Learning in strategic settings / game theory

# Some concerns about LLMs

- Overconfidence / hallucination / BS
  - It does not know what it does not know...
  - ... or at least doesn't indicate this
- Stealing / leaking / lack of attribution
- Cybersecurity / bot armies / flood of communication / other malicious uses
- Loss of signal in text being written (cf. deepfakes)
  - College essays
  - Job applications
  - ...
- Environmental cost / cheap outsourcing of human labor / ...
- Inheriting human biases / uneven training data across languages and cultures
- Harmful speech / manipulating and deceiving humans
- Humans overinterpreting responses / getting directed into real-world action
- A new general / difficult-to-direct intelligence
- ...

# Unlearning (!)

<https://unlearning-challenge.github.io/>
