Warm-up as You Walk In (Repeat)

Given

- Set actions (persistent/static)
- Set states (persistent/static)
- Function T(s,a,s_prime)

Write the pseudo code for:

■ function V(s) return value

that implements:

$$V(s) = \max_{a \in actions} \sum_{s' \in states} T(s, a, s')V(s')$$

AI: Representation and Problem Solving

Markov Decision Processes II

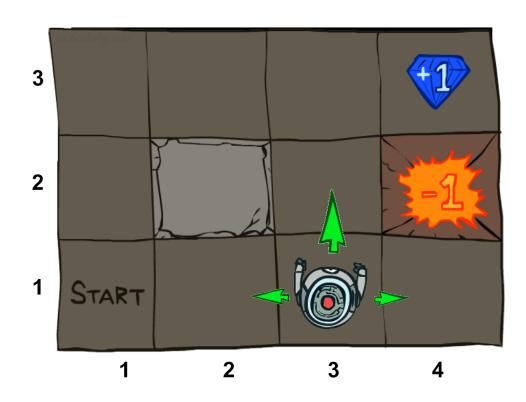

Instructors: Pat Virtue & Stephanie Rosenthal

Slide credits: CMU AI and http://ai.berkeley.edu

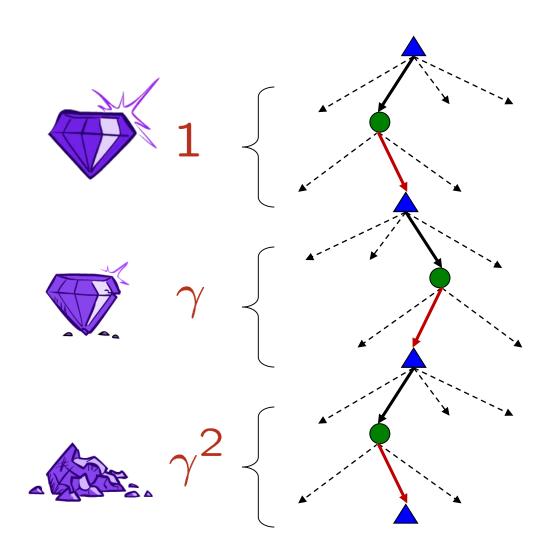

Example: Grid World

- A maze-like problem
 - The agent lives in a grid
 - Walls block the agent's path
- Noisy movement: actions do not always go as planned
 - 80% of the time, the action North takes the agent North
 - 10% of the time, North takes the agent West; 10% East
 - If there is a wall in the direction the agent would have been taken, the agent stays put
- The agent receives rewards each time step
 - Small "living" reward each step (can be negative)
 - Big rewards come at the end (good or bad)

Example: Grid World

- A maze-like problem
 - The agent lives in a grid
 - Walls block the agent's path
- Noisy movement: actions do not always go as planned
 - 80% of the time, the action North takes the agent North
 - 10% of the time, North takes the agent West; 10% East
 - If there is a wall in the direction the agent would have been taken, the agent stays put
- The agent receives rewards each time step
 - Small "living" reward each step (can be negative)
 - Big rewards come at the end (good or bad)
- Goal: maximize sum of (discounted) rewards

Recap: MDPs

Markov decision processes:

- States S
- Actions A
- Transitions P(s' s,a) (or T(s,a,s'))
- Rewards R(s,a,s') (and discount γ)
- Start state s₀

Max s,a,s

Quantities:

- Policy = map of states to actions
- Utility = sum of discounted rewards
- Values = expected future utility from a state (max node)
- Q-Values = expected future utility from a q-state (chance node)

MDP Notation

Standard expectimax:
$$V(s) = \max_{a} \sum_{s} P(s'|s, a)V(s')$$

Bellman equations:
$$V(s) = \max_{a} \sum_{s'}^{s'} P(s'|s,a) [R(s,a,s') + \gamma V(s')]$$

Value iteration:
$$V_{k+1}(s) = \max_{a} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V_k(s')], \quad \forall$$

Q-iteration:
$$Q_{k+1}(s,a) = \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma \max_{a'} Q_k(s',a')], \quad \forall s,a$$

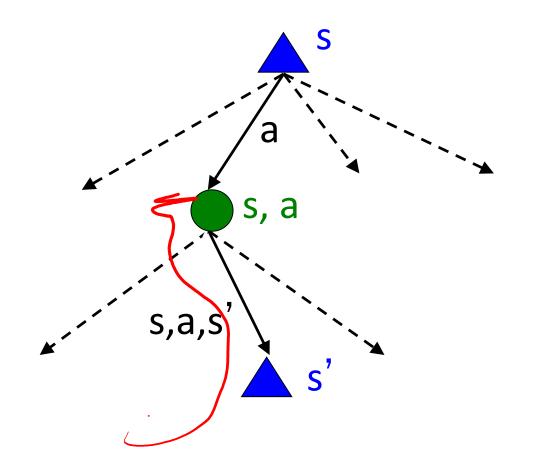

Policy extraction:
$$\pi_V(s) = \underset{a}{\operatorname{argmax}} \sum_{S'} P(s'|s,a) [R(s,a,s') + \gamma V(s')], \quad \forall s$$

Policy evaluation:
$$V_{k+1}^{\pi}(s) = \sum_{s'} P(s'|s,\pi(s))[R(s,\pi(s),s') + \gamma V_k^{\pi}(s')], \quad \forall s$$

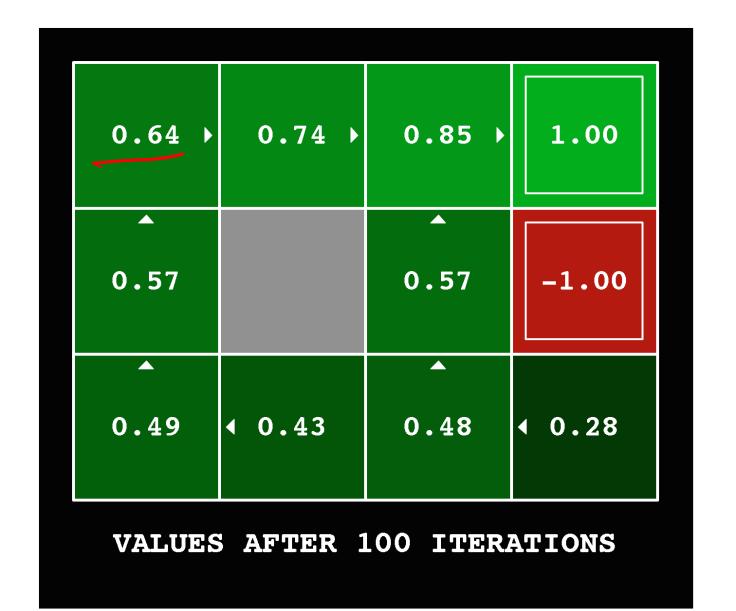

Policy improvement:
$$\pi_{new}(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V^{\pi_{old}}(s')], \quad \forall s'$$

Optimal Quantities

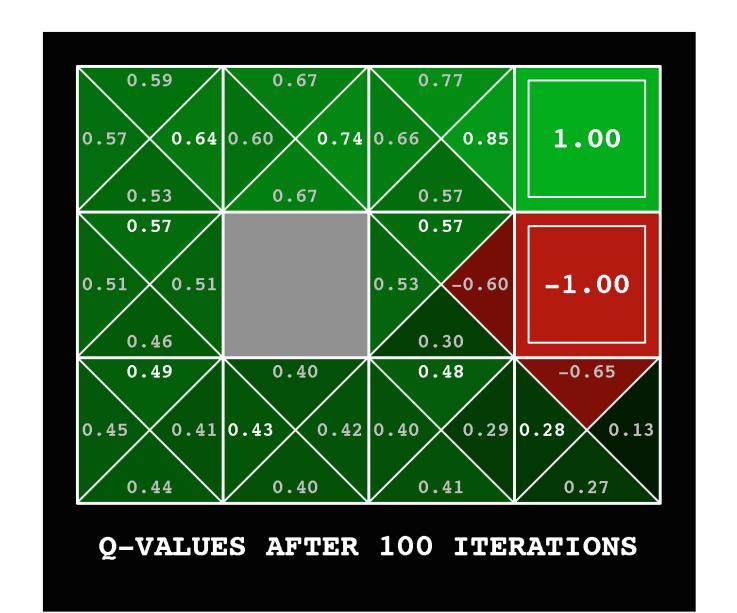

- The value (utility) of a state s:
 - V*(s) = expected utility starting in s and acting optimally
- The value (utility) of a q-state (s,a):
 - Q*(s,a) = expected utility starting out having taken action a from state s and (thereafter) acting optimally
- The optimal policy:
 - $\pi^*(s)$ = optimal action from state s

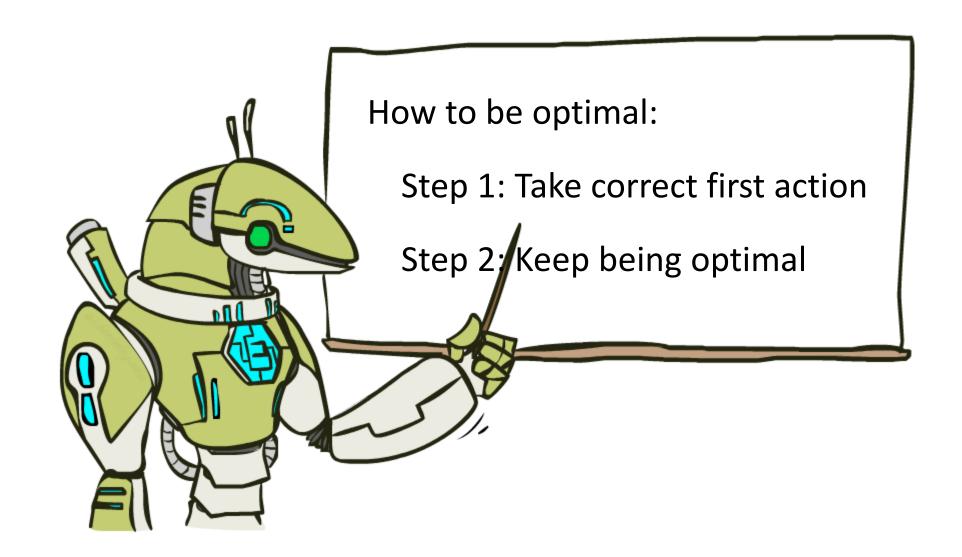

Gridworld Values V*

Gridworld: Q*

The Bellman Equations

The Bellman Equations

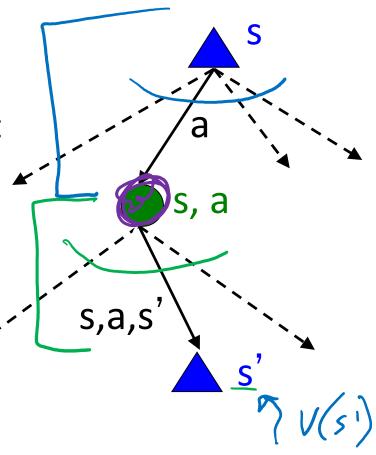

Definition of "optimal utility" via expectimax recurrence gives a simple one-step lookahead relationship amongst optimal utility values

$$V^*(s) = \max_{a} Q^*(s, a)$$

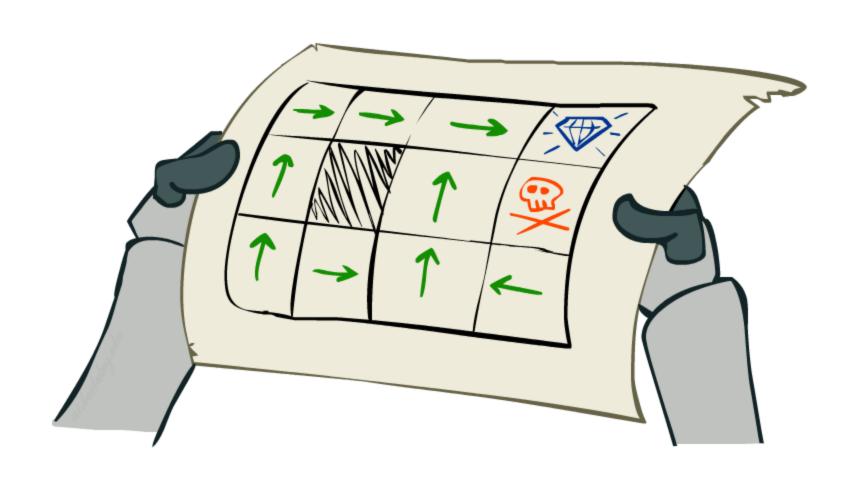

$$Q^*(s, a) = \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V^*(s') \right]$$

$$V^*(s) = \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V^*(s') \right]$$

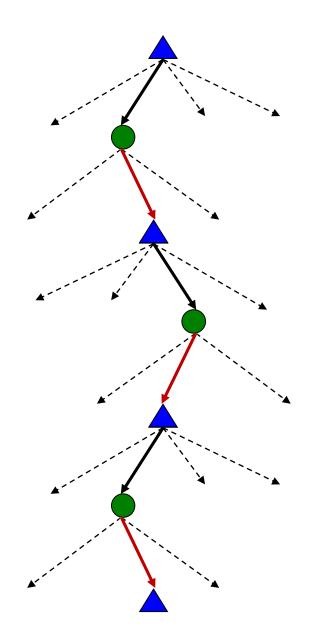

These are the Bellman equations, and they characterize optimal values in a way we'll use over and over

Solving MDPs

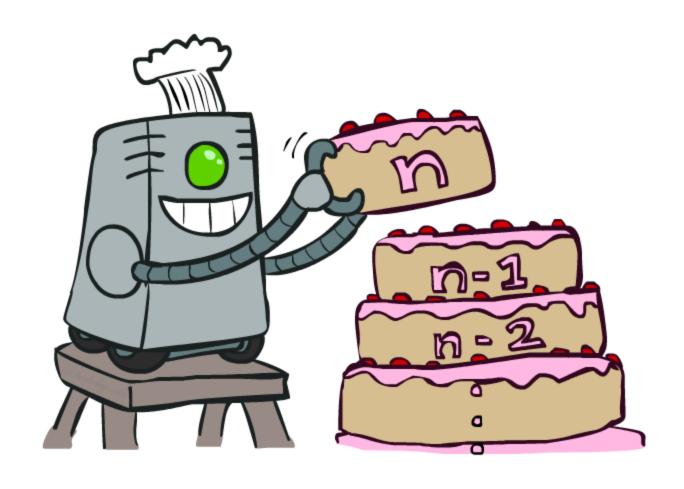

Solving Expectimax

Solving Expectimax

Solving Expectimax

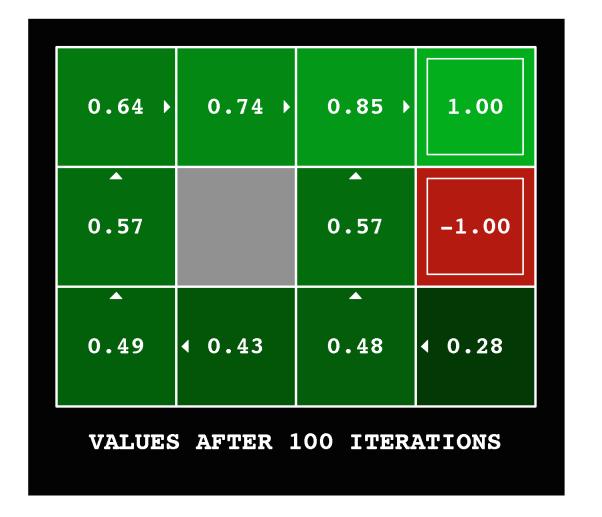

Value Iteration

_	A	<u> </u>	A		
0.00	0.00	0.00	0.00		
VALUES AFTER 0 ITERATIONS					

Value Iteration

Start with $V_0(s) = 0$: no time steps left means an expected reward sum of zero

Given vector of $V_k(s)$ values, do one ply of expectimax from each state:

$$V_{k+1}(s) \leftarrow \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V_k(s') \right]$$

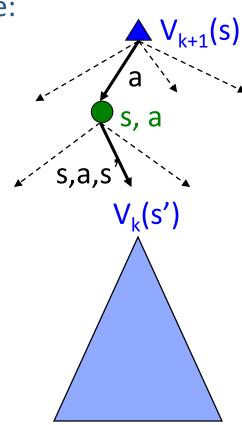

Repeat until convergence

554

Complexity of each iteration: O(S²A)

Theorem: will converge to unique optimal values

- Basic idea: approximations get refined towards optimal values
- Policy may converge long before values do

Value Iteration

Bellman equations characterize the optimal values:

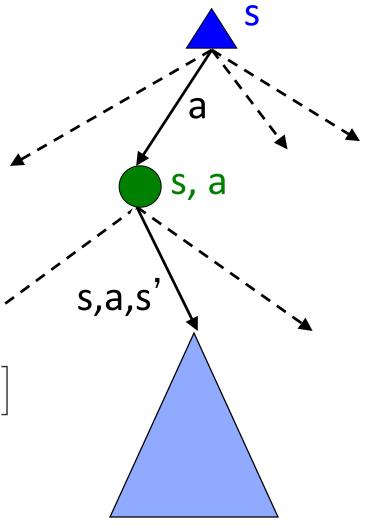

$$V^*(s) = \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V^*(s') \right]$$

Value iteration computes them:

$$V_{k+1}(s) \leftarrow \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V_k(s') \right]$$

Value iteration is just a fixed point solution method

■ ... though the V_k vectors are also interpretable as time-limited values

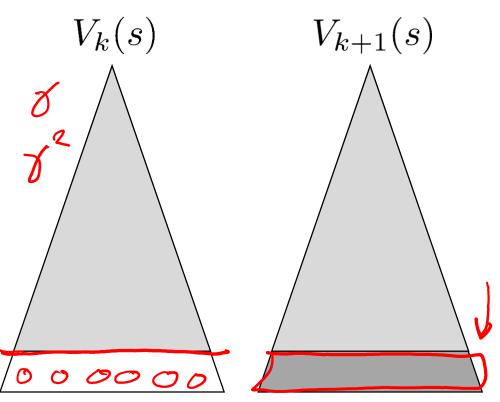

Value Iteration Convergence

How do we know the V_k vectors are going to converge?

Case 1: If the tree has maximum depth M, then V_M holds the actual untruncated values

Case 2: If the discount is less than 1

- Sketch: For any state V_k and V_{k+1} can be viewed as depth k+1 expectimax results in nearly identical search trees
- The difference is that on the bottom layer, V_{k+1} has actual rewards while V_k has zeros
- That last layer is at best all R_{MAX}
- It is at worst R_{MIN}
- But everything is discounted by γ^k that far out
- So V_k and V_{k+1} are at most γ^k max |R| different
- So as k increases, the values converge

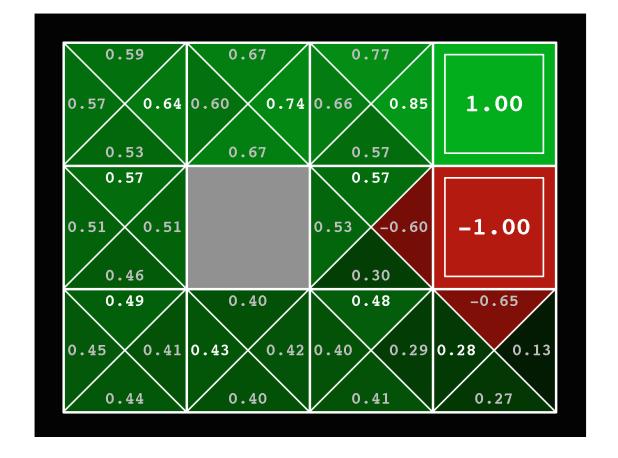

Solved MDP! Now what?

What are we going to do with these values??

$$V^*(s)$$

 $Q^*(s,a)$

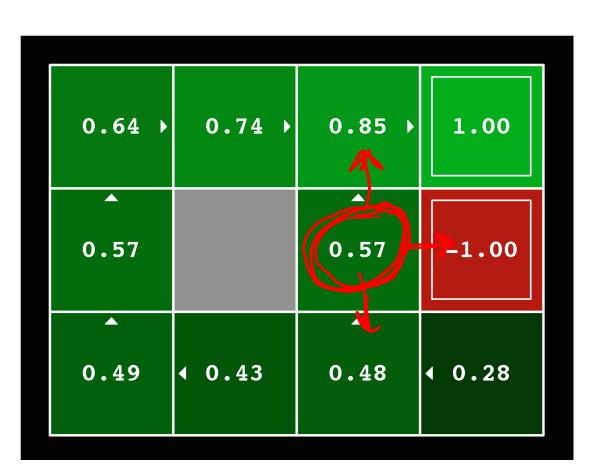

Piazza Poll 1

 $n(5) = \underset{a}{\text{arg max}} Q(s, a)$

If you need to extract a policy, would you rather have

Values or Q-values?

Values or Q-values?

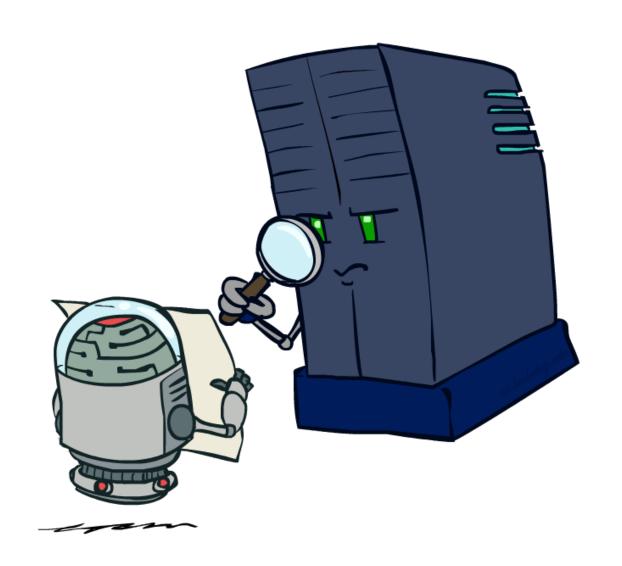

Policy Methods

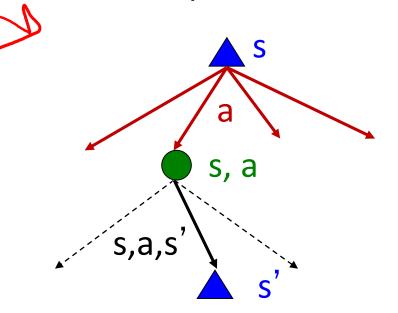

Policy Evaluation

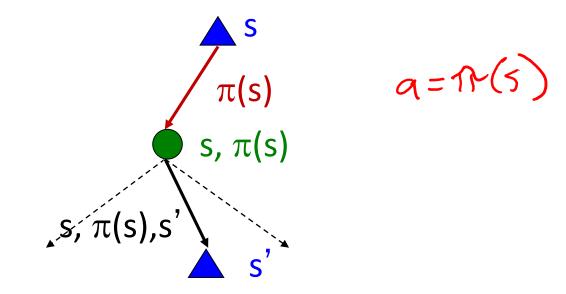

Fixed Policies

Do the optimal action

Do what π says to do

Expectimax trees max over all actions to compute the optimal values

If we fixed some policy $\pi(s)$, then the tree would be simpler

- only one action per state
- ... though the tree's value would depend on which policy we fixed

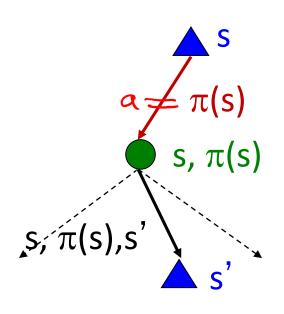

Utilities for a Fixed Policy

Another basic operation: compute the utility of a state s under a fixed (generally non-optimal) policy

Define the utility of a state s, under a fixed policy π :

 $V^{\pi}(s)$ = expected total discounted rewards starting in s and following π

Recursive relation (one-step look-ahead / Bellman equation):

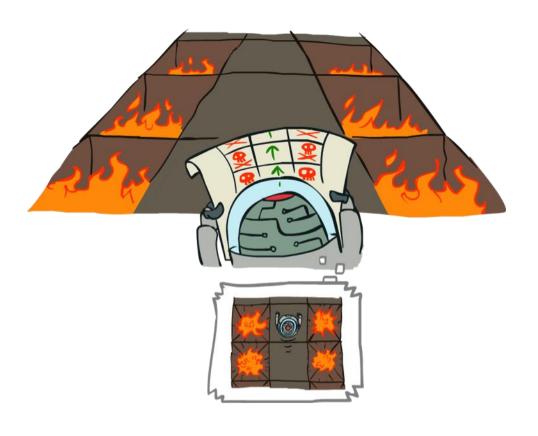

$$V^{\pi}(s) = \sum_{s'} T(s, \underline{\pi(s)}, s') [R(s, \underline{\pi(s)}, s') + \gamma V^{\pi}(s')]$$

Example: Policy Evaluation

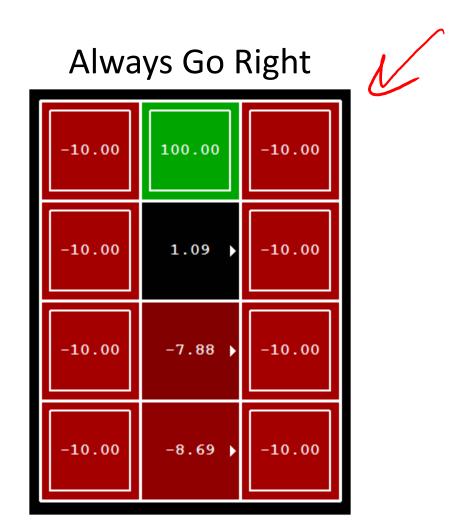

Always Go Right

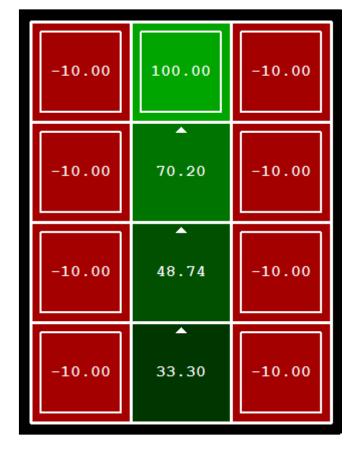

Always Go Forward

Example: Policy Evaluation

Always Go Forward

Policy Evaluation

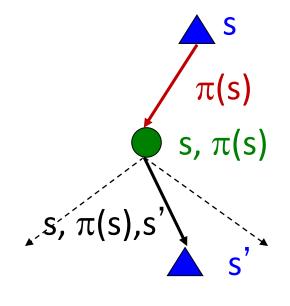

How do we calculate the V's for a fixed policy π ?

Idea 1: Turn recursive Bellman equations into updates (like value iteration)

$$V_0^{\pi}(s) = 0$$

$$V_{k+1}^{\pi}(s) \leftarrow \sum_{s'} T(s, \pi(s), s') [R(s, \pi(s), s') + \gamma V_k^{\pi}(s')]$$

$$5.5$$

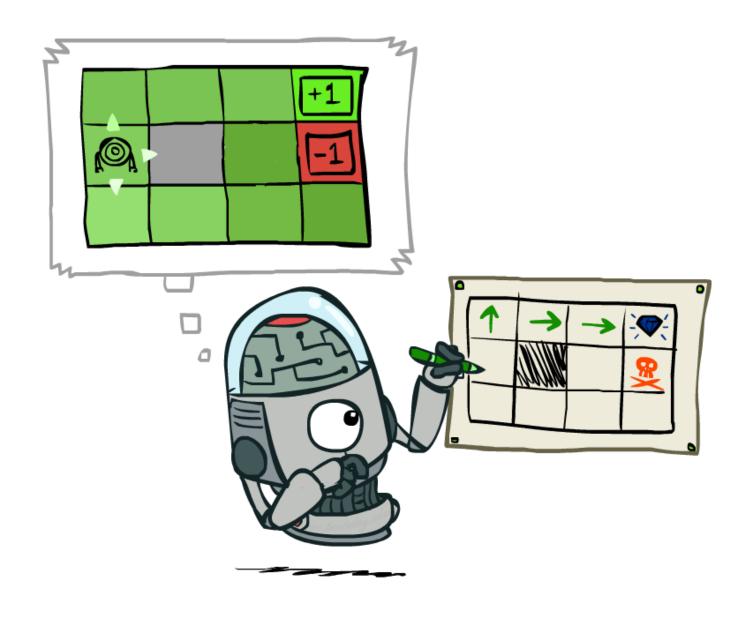

Efficiency: O(S²) per iteration

Idea 2: Without the maxes, the Bellman equations are just a linear system

Solve with your favorite linear system solver

Policy Extraction

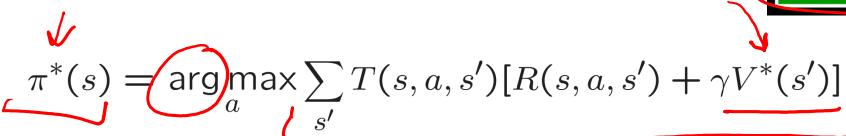

Computing Actions from Values

Let's imagine we have the optimal values V*(s)

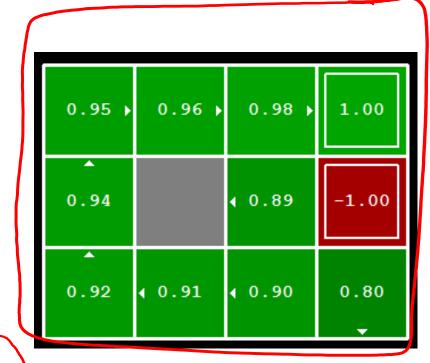

How should we act?

It's not obvious!

We need to do a mini-expectimax (one step)

This is called policy extraction, since it gets the policy implied by the values

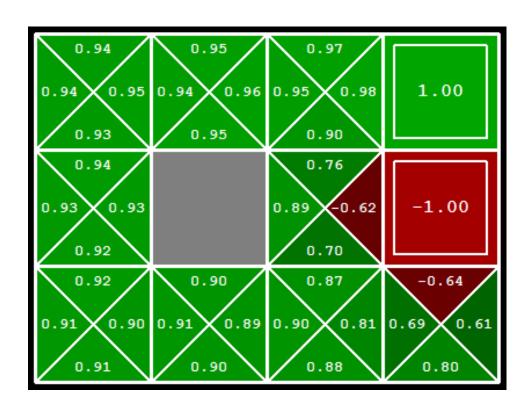

Computing Actions from Q-Values

Let's imagine we have the optimal q-values:

How should we act?

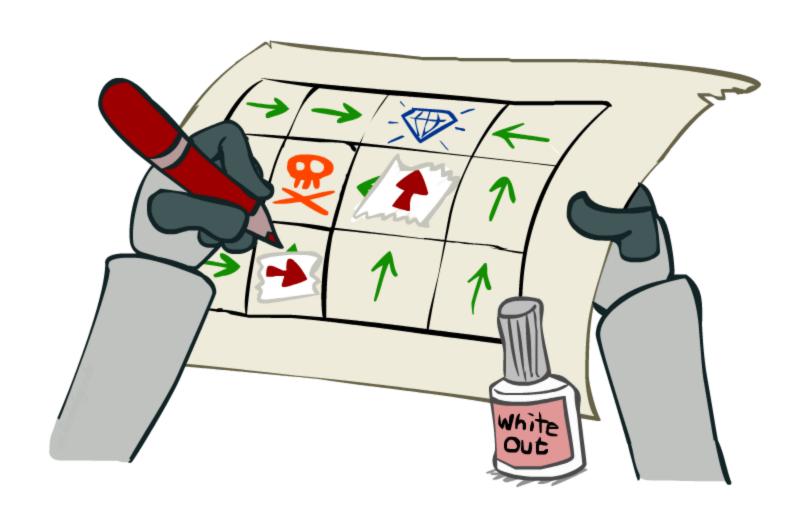

Completely trivial to decide!

$$\pi^*(s) = \underset{a}{\operatorname{arg\,max}} \, Q^*(s, a)$$

Important lesson: actions are easier to select from q-values than values!

Policy Iteration

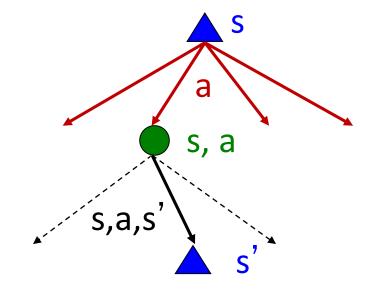

Problems with Value Iteration

Value iteration repeats the Bellman updates:

$$V_{k+1}(s) \leftarrow \max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V_k(s') \right]$$

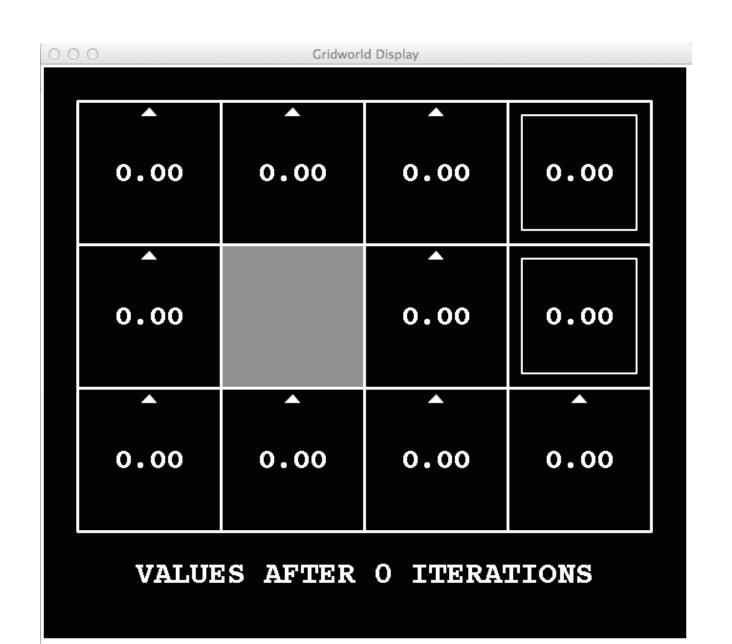

Problem 1: It's slow – O(S²A) per iteration

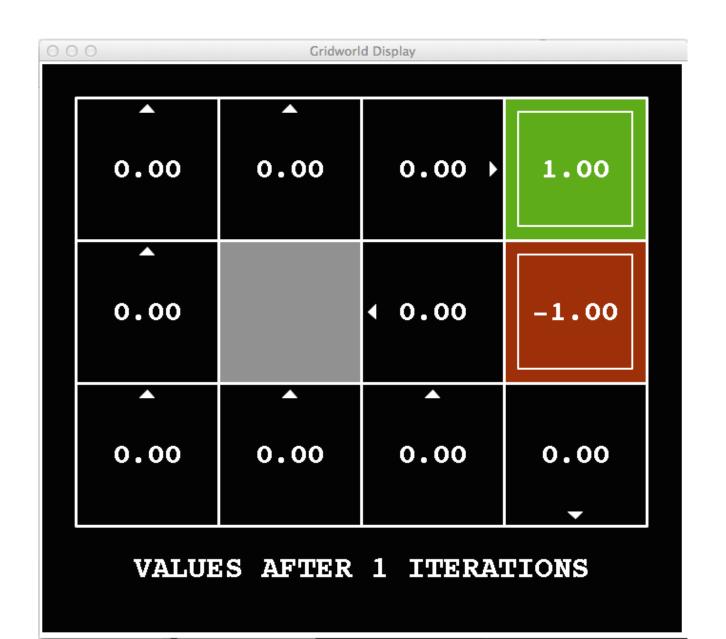

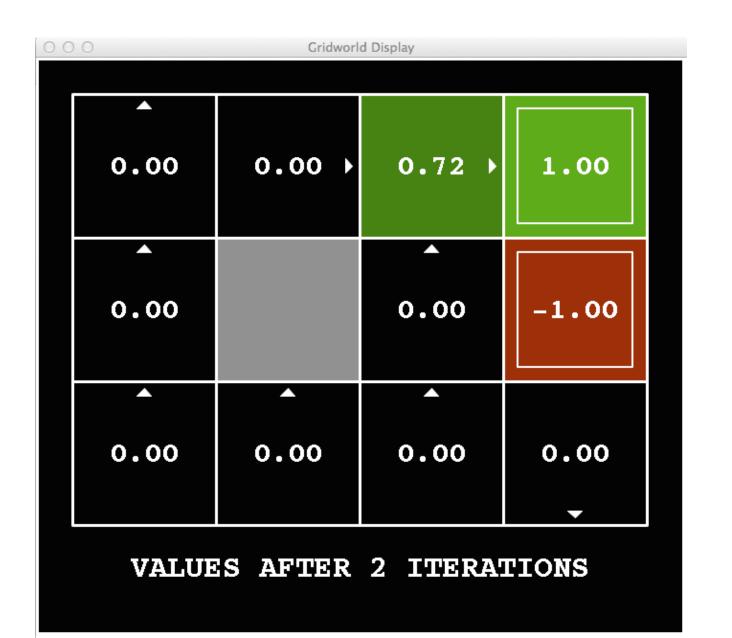

Problem 2: The "max" at each state rarely changes

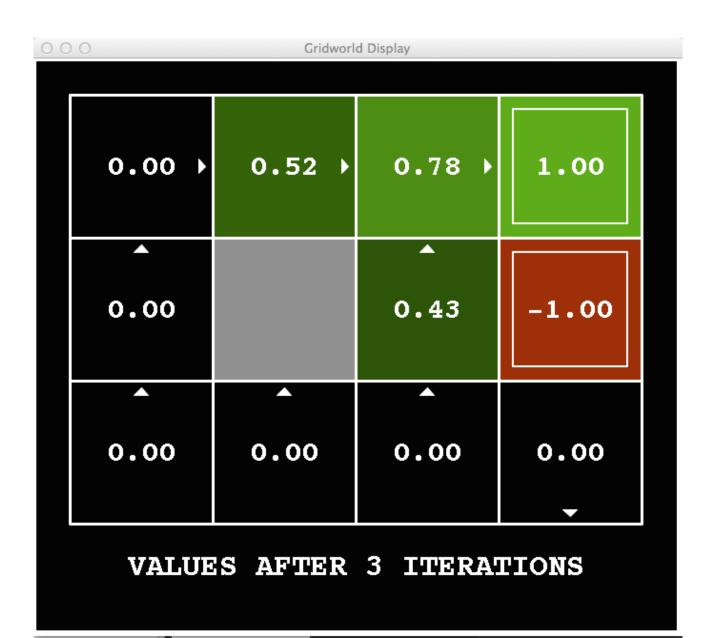

Problem 3: The policy often converges long before the values

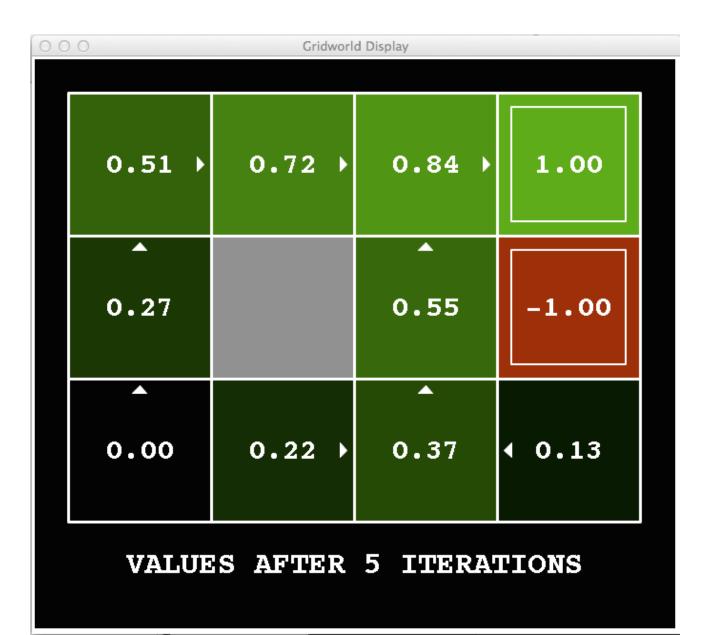

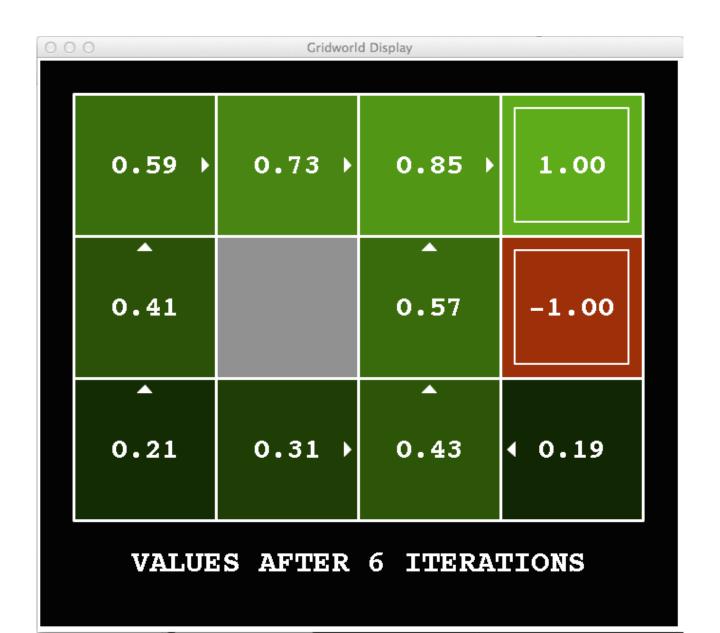

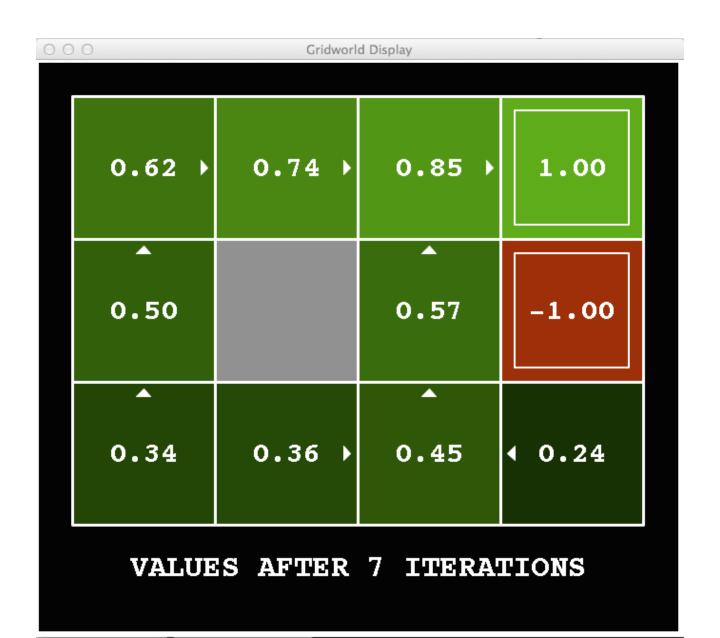

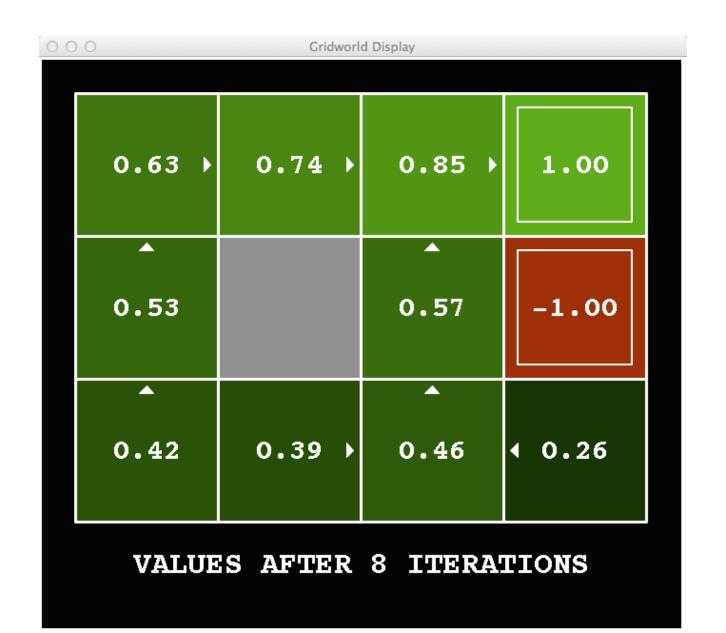

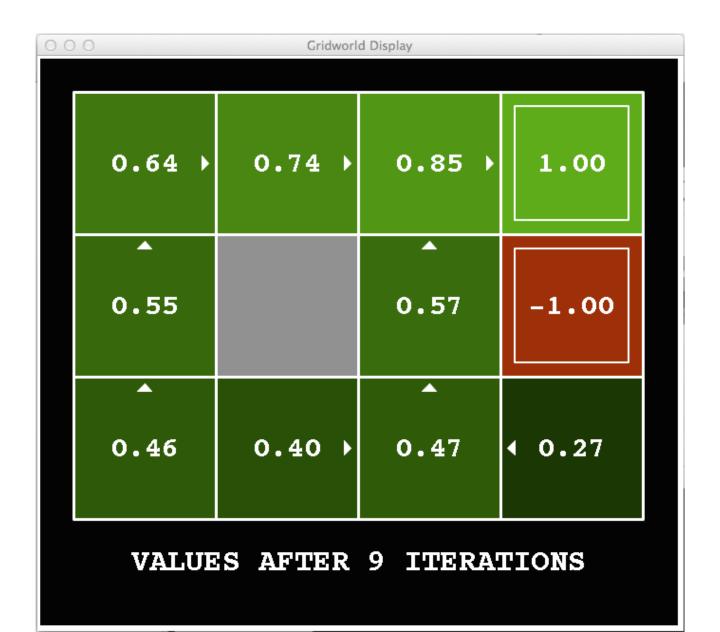

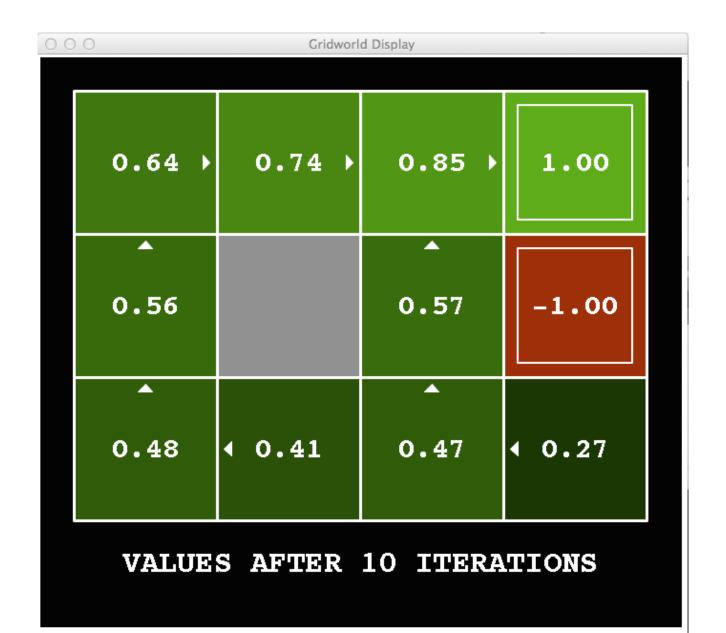

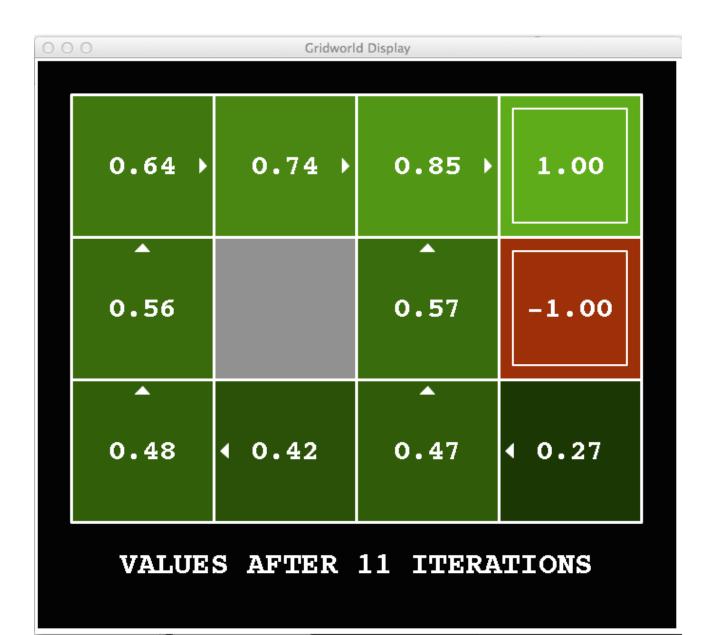

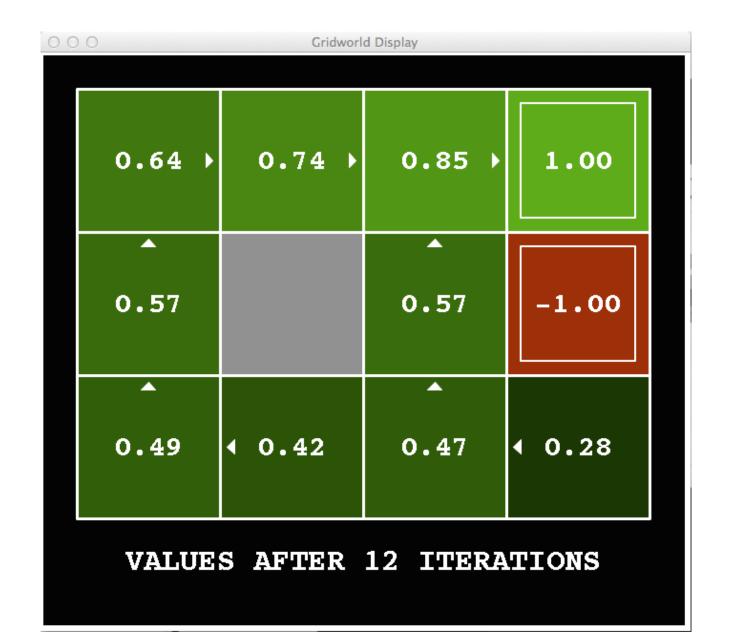

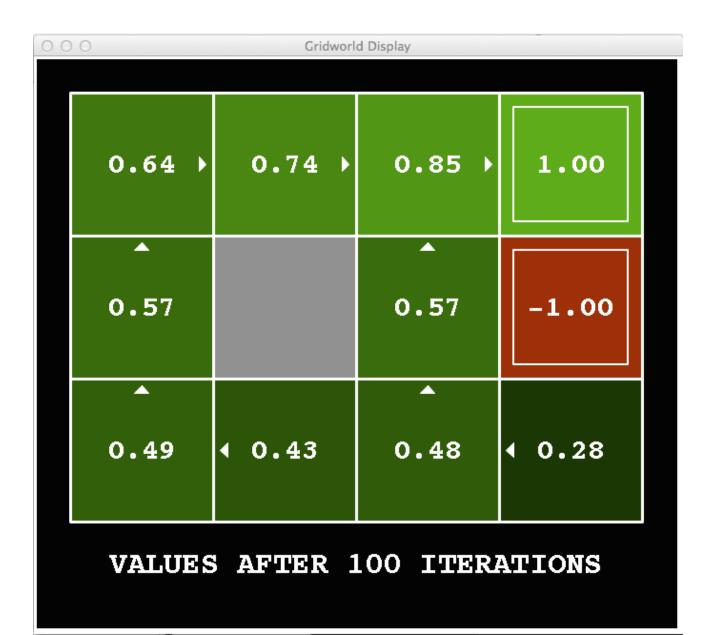

k = 10

k = 11

Policy Iteration

Alternative approach for optimal values:

- Step 1: Policy evaluation: calculate utilities for some fixed policy (not optimal utilities!) until convergence
- Step 2: Policy improvement: update policy using one-step look-ahead with resulting converged (but not optimal!) utilities as future values
- Repeat steps until policy converges

This is policy iteration

- It's still optimal!
- Can converge (much) faster under some conditions

Policy Iteration

Evaluation: For fixed current policy π , find values with policy evaluation:

Iterate until values converge:

$$V_{k+1}^{\pi_i}(s) \leftarrow \sum_{s'} T(s, \pi_i(s), s') \left[R(s, \pi_i(s), s') + \gamma V_k^{\pi_i}(s') \right]$$

Improvement: For fixed values, get a better policy using policy extraction

One-step look-ahead:

$$\pi_{i+1}(s) = \arg\max_{a} \sum_{s'} T(s, a, s') \left[R(s, a, s') + \gamma V^{\pi_i}(s') \right]$$

Comparison

Both value iteration and policy iteration compute the same thing (all optimal values)

In value iteration:

- Every iteration updates both the values and (implicitly) the policy
- We don't track the policy, but taking the max over actions implicitly recomputes it

In policy iteration:

- We do several passes that update utilities with fixed policy (each pass is fast because we consider only one action, not all of them)
- After the policy is evaluated, a new policy is chosen (slow like a value iteration pass)
- The new policy will be better (or we're done)

(Both are dynamic programs for solving MDPs)

Summary: MDP Algorithms

So you want to....

- Compute optimal values: use value iteration or policy iteration
- Compute values for a particular policy: use policy evaluation
- Turn your values into a policy: use policy extraction (one-step lookahead)

These all look the same!

- They basically are they are all variations of Bellman updates
- They all use one-step lookahead expectimax fragments
- They differ only in whether we plug in a fixed policy or max over actions

Standard expectimax:
$$V(s) = \max_{a} \sum_{s} P(s'|s,a)V(s')$$

Bellman equations:
$$V(s) = \max_{a} \sum_{s'} P(s'|s,a)[R(s,a,s') + \gamma V(s')]$$

Value iteration:
$$V_{k+1}(s) = \max_{a} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V_k(s')], \quad \forall s$$

Q-iteration:
$$Q_{k+1}(s,a) = \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma \max_{a'} Q_k(s',a')], \quad \forall s,a$$

Policy extraction:
$$\pi_V(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V(s')], \quad \forall s$$

Policy evaluation:
$$V_{k+1}^{\pi}(s) = \sum_{s'} P(s'|s,\pi(s))[R(s,\pi(s),s') + \gamma V_k^{\pi}(s')], \quad \forall s$$

Policy improvement:
$$\pi_{new}(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V^{\pi_{old}}(s')], \quad \forall s'$$

Standard expectimax:
$$V(s) = \max_{a} \sum_{s} P(s'|s, a)V(s')$$

Bellman equations:
$$V(s) = \max_{a} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V(s')]$$

Value iteration:
$$V_{k+1}(s) = \max_{a} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V_k(s')], \quad \forall s$$

Q-iteration:
$$Q_{k+1}(s,a) = \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma \max_{a'} Q_k(s',a')], \quad \forall s,a$$

Policy extraction:
$$\pi_V(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V(s')], \quad \forall s$$

Policy evaluation:
$$V_{k+1}^{\pi}(s) = \sum_{s'} P(s'|s,\pi(s))[R(s,\pi(s),s') + \gamma V_k^{\pi}(s')], \quad \forall s \in \mathbb{R}$$

Policy improvement:
$$\pi_{new}(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V^{\pi_{old}}(s')], \quad \forall s'$$

Standard expectimax:
$$V(s) = \max_{a} \sum_{s} P(s'|s,a)V(s')$$

Bellman equations:
$$V(s) = \max_{a} \sum_{s'} P(s'|s,a)[R(s,a,s') + \gamma V(s')]$$

Value iteration:
$$V_{k+1}(s) = \max_{a} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V_k(s')], \quad \forall s$$

Q-iteration:
$$Q_{k+1}(s,a) = \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma \max_{a'} Q_k(s',a')], \quad \forall s,a$$

Policy extraction:
$$\pi_V(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V(s')], \quad \forall s$$

Policy evaluation:
$$V_{k+1}^{\pi}(s) = \sum_{s'} P(s'|s,\pi(s))[R(s,\pi(s),s') + \gamma V_k^{\pi}(s')], \quad \forall s$$

Policy improvement:
$$\pi_{new}(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V^{\pi_{old}}(s')], \quad \forall s'$$

$$V(s) = \max_{a} \sum_{s'} P(s'|s, a)V(s')$$

$$V(s) = \max_{a} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V(s')]$$

$$V_{k+1}(s) = \max_{a} \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma V_{k}(s')], \quad \forall s$$

$$Q_{k+1}(s,a) = \sum_{s'} P(s'|s,a) [R(s,a,s') + \gamma \max_{a'} Q_k(s',a')], \quad \forall \, s, a$$

$$\pi_{V}(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s, a) [R(s, a, s') + \gamma V(s')], \quad \forall s$$

$$V_{k+1}^{\pi}(s) = \sum_{s'} P(s'|s, \pi(s)) [R(s, \pi(s), s') + \gamma V_k^{\pi}(s')], \quad \forall s'$$

$$\pi_{new}(s) = \underset{a}{\operatorname{argmax}} \sum_{s'} P(s'|s, a) [R(s, a, s') + \gamma V^{\pi_{old}}(s')], \quad \forall s$$

Double Bandits

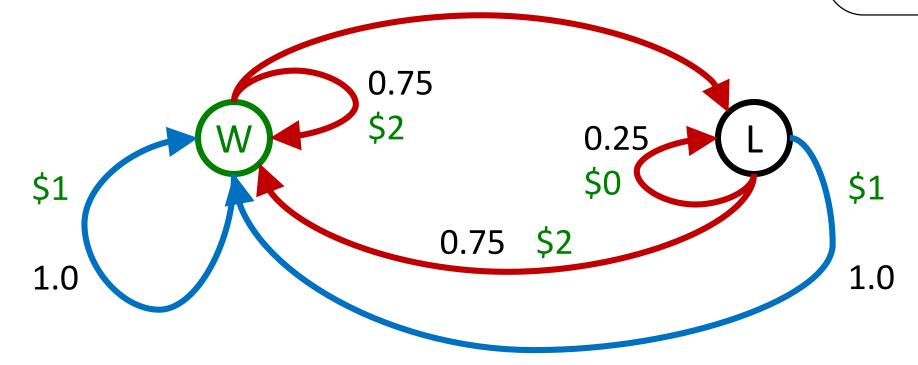

Double-Bandit MDP

Actions: Blue, Red

States: Win, Lose

No discount
100 time steps
Both states have
the same value

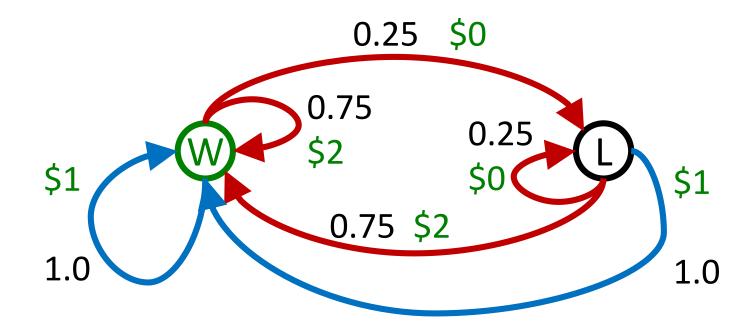

Offline Planning

Solving MDPs is offline planning

- You determine all quantities through computation
- You need to know the details of the MDP
- You do not actually play the game!

No discount
100 time steps
Both states have
the same value

Let's Play!

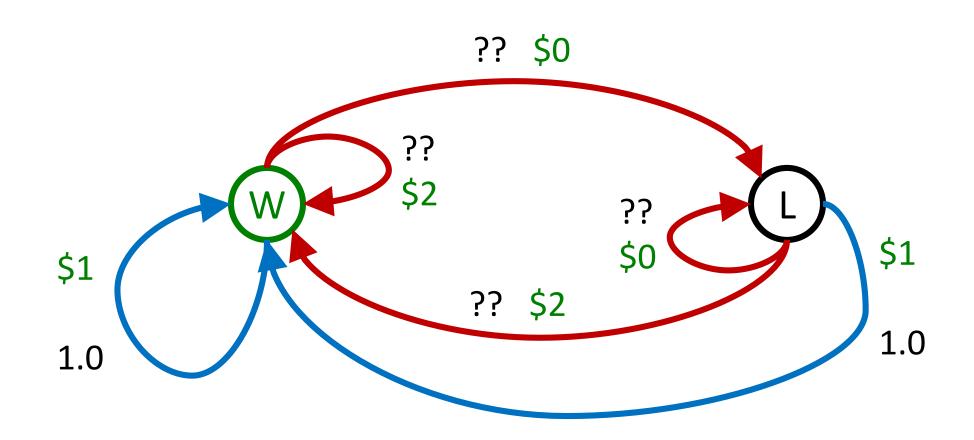

\$2 \$2 \$0 \$2 \$2

\$2 \$2 \$0 \$0 \$0

Online Planning

Rules changed! Red's win chance is different.

Let's Play!

\$0 \$0 \$0 \$2 \$0

\$2 \$0 \$0 \$0 \$0

What Just Happened?

That wasn't planning, it was learning!

- Specifically, reinforcement learning
- There was an MDP, but you couldn't solve it with just computation
- You needed to actually act to figure it out

Important ideas in reinforcement learning that came up

- Exploration: you have to try unknown actions to get information
- Exploitation: eventually, you have to use what you know
- Regret: even if you learn intelligently, you make mistakes
- Sampling: because of chance, you have to try things repeatedly
- Difficulty: learning can be much harder than solving a known MDP

Next Time: Reinforcement Learning!
