## Warm-up as you walk in

Write the pseudo code for breadth first search and depth first search

Iterative version, not recursive

```
class TreeNode
    TreeNode[] children()
    boolean isGoal()

BFS(TreeNode start)...

DFS(TreeNode start)...
```

### Announcements

If you are not on Piazza, Gradescope, and Canvas

E-mail me: pvirtue@cmu.edu

No class next Mon 1/21, MLK Holiday

Recitation starting this Fri 3pm, GHC 4401 (recommended)

- Bring laptop if you can (not required)
- Start P0 before recitation to make sure Python 3.6 is working for you!

Reminder to be respectful of quiet areas in campus buildings

### Announcements

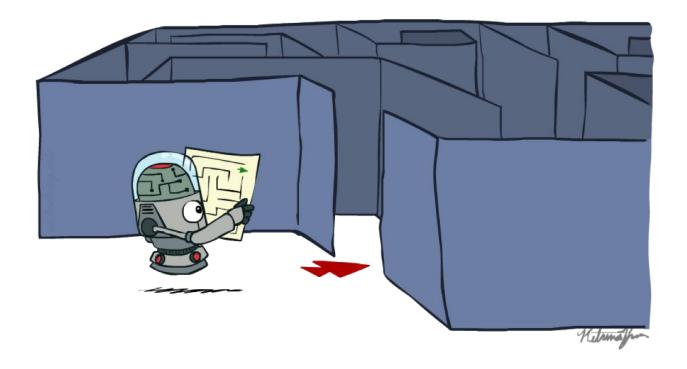

### Assignments:

- HW1 (online)
  - Released at 4:30 pm today
  - Due Tue 1/22, 10 pm
- P0: Python & Autograder Tutorial
  - Required, but worth zero points
  - Due Thu 1/24, 10 pm
  - No pairs, submit individually

Remaining programming assignments may be done in pairs

# AI: Representation and Problem Solving

# Agents and Search

Instructors: Pat Virtue & Stephanie Rosenthal

Slide credits: CMU AI, http://ai.berkeley.edu

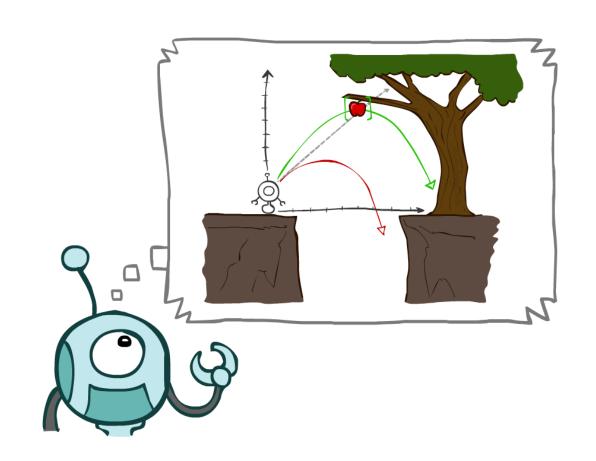

# Today

## Agents and Environment

### Search Problems

## **Uninformed Search Methods**

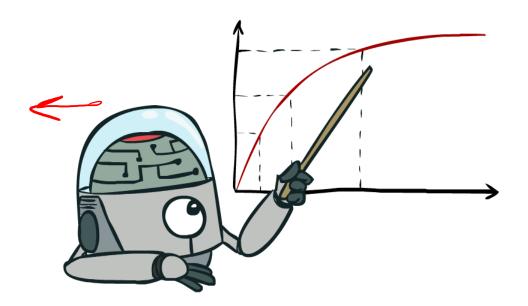

- Depth-First Search
- Breadth-First Search
- Uniform-Cost Search

## Rationality, contd.

### What is rational depends on:

- Performance measure
- Agent's prior knowledge of environment
- Actions available to agent
- Percept sequence to date

Being rational means maximizing your expected utility

## Rational Agents

### Are rational agents *omniscient*?

■ No – they are limited by the available percepts

### Are rational agents *clairvoyant*?

■ No – they may lack knowledge of the environment dynamics

### Do rational agents *explore* and *learn*?

Yes – in unknown environments these are essential

So rational agents are not necessarily successful, but they are autonomous (i.e., transcend initial program)

### Task Environment - PEAS

#### Performance measure

-1 per step; +10 food; +500 win; -500 die;
 +200 hit scared ghost

#### **Environment**

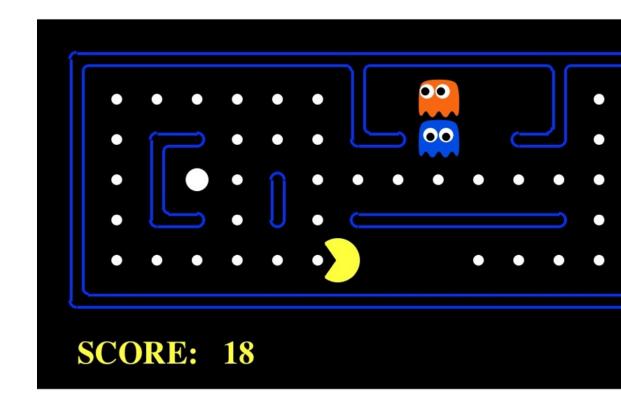

Pacman dynamics (incl ghost behavior)

#### **Actuators**

North, South, East, West, (Stop)

#### Sensors

Entire state is visible

### PEAS: Automated Taxi

#### Performance measure

 Income, happy customer, vehicle costs, fines, insurance premiums

#### **Environment**

US streets, other drivers, customers

#### **Actuators**

Steering, brake, gas, display/speaker

#### Sensors

 Camera, radar, accelerometer, engine sensors, microphone

# **Environment Types**

	Pacman	Taxi
Fully or partially observable	full	partial
Single agent or multi-agent	multi	multi
Deterministic or stochastic	deterministic	stochas-11C
Static or dynamic	static	dynamic
Discrete or continuous	discrete	Cont

## Reflex Agents

### Reflex agents:

- Choose action based on current percept (and maybe memory)
- May have memory or a model of the world's current state
- Do not consider the future consequences of their actions
- Consider how the world IS ←

Can a reflex agent be rational?

[Demo: reflex optimal (L2D1)]

[Demo: reflex optimal (L2D2)]

# Demo Reflex Agent

[Demo: reflex optimal (L2D1)]

[Demo: reflex optimal (L2D2)]

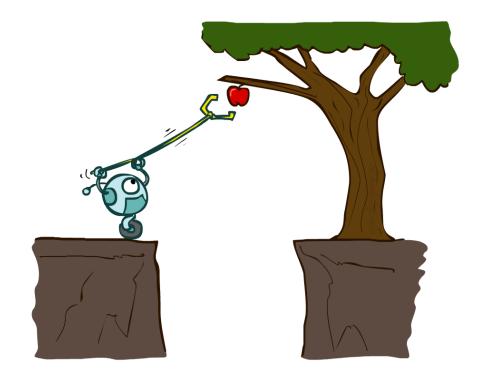

## Agents that Plan Ahead

### Planning agents:

- Decisions based on predicted consequences of actions
- Must have a transition model: how the world evolves in response to actions
- Must formulate a goal
- Consider how the world WOULD BE

### Spectrum of deliberativeness:

- Generate complete, optimal plan offline, then execute
- Generate a simple, greedy plan, start executing, replan when something goes wrong

# Search Problems

### Search Problems

### A search problem consists of:

A state space

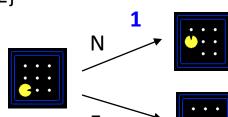

For each state, a setActions(s) of allowable actions

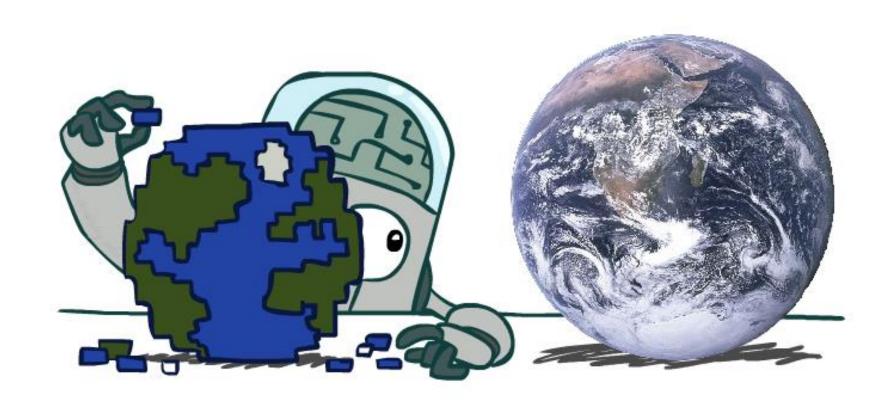

{N, E}

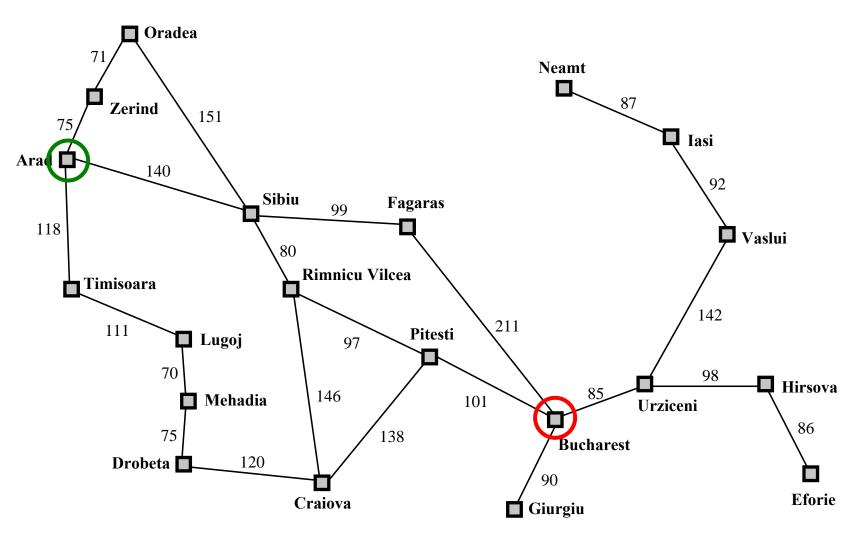

- A transition model Result(s,a)
- A step cost function c(s,a,s')
- A start state and a goal test

A solution is a sequence of actions (a plan) which transforms the start state to a goal state

## Search Problems Are Models

# Example: Travelling in Romania

#### State space:

Cities

#### **Actions:**

Go to adjacent city

#### Transition model

• Result(A, Go(B)) = B

### Step cost

Distance along road link

#### Start state:

Arad

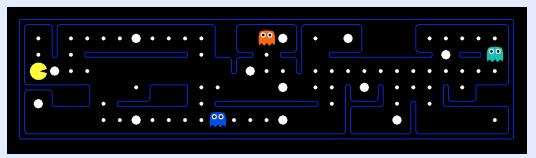

#### Goal test:

Is state == Bucharest?

#### Solution?

# What's in a State Space?

The real world state includes every last detail of the environment

A search state abstracts away details not needed to solve the problem

- Problem: Pathing
  - State representation: (x,y) location
  - Actions: NSEW
  - Transition model: update location
  - Goal test: is (x,y)=END

- Problem: Eat-All-Dots
  - State representation: {(x,y), dot booleans}
  - Actions: NSEW
  - Transition model: update location and possibly a dot boolean
  - Goal test: dots all false

## State Space Sizes?

### World state:

Agent positions: 120

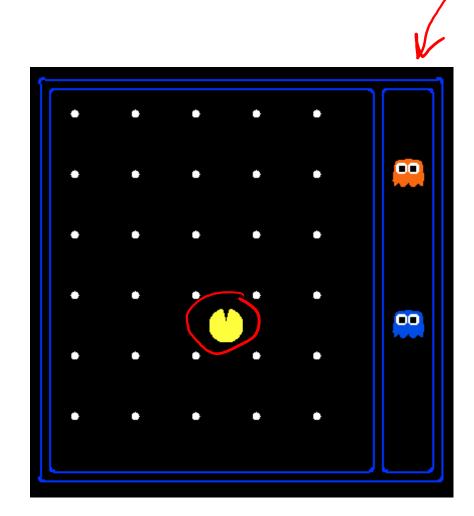

■ Food count: 30

• Ghost positions: 12

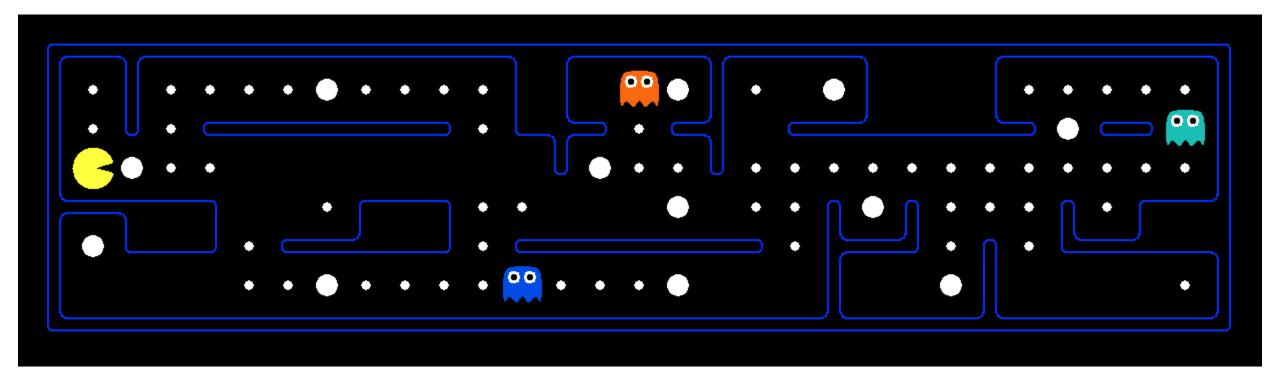

Agent facing: NSEW

### How many

- World states?
   120x(2<sup>30</sup>)x(12<sup>2</sup>)x4
- States for pathing?120
- States for eat-all-dots? 120x(2<sup>30</sup>)

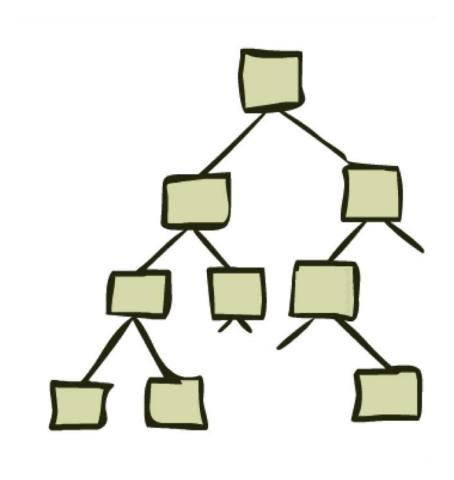

## Safe Passage

Problem: eat all dots while keeping the ghosts perma-scared What does the state representation have to specify?

(agent position, dot booleans, power pellet booleans, remaining scared time)

# State Space Graphs and Search Trees

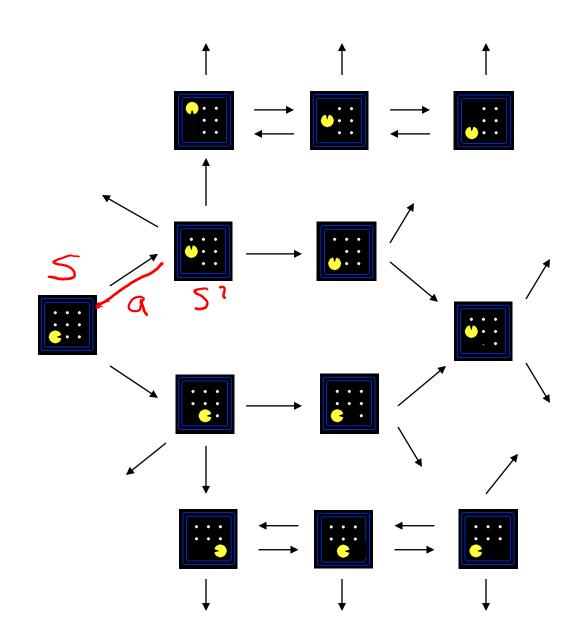

## State Space Graphs

# State space graph: A mathematical representation of a search problem

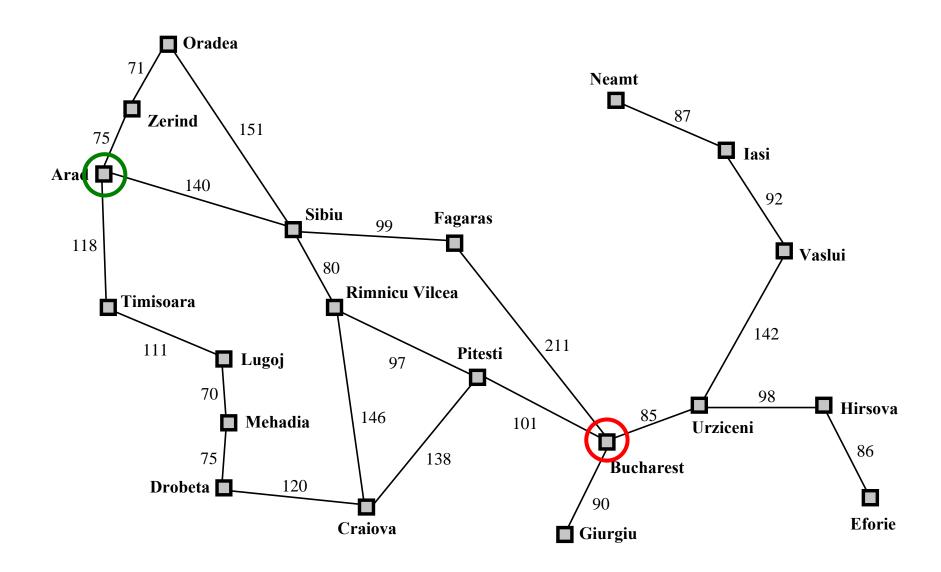

- Nodes are (abstracted) world configurations
- Arcs represent transitions resulting from actions
- The goal test is a set of goal nodes (maybe only one)

In a state space graph, each state occurs only once!

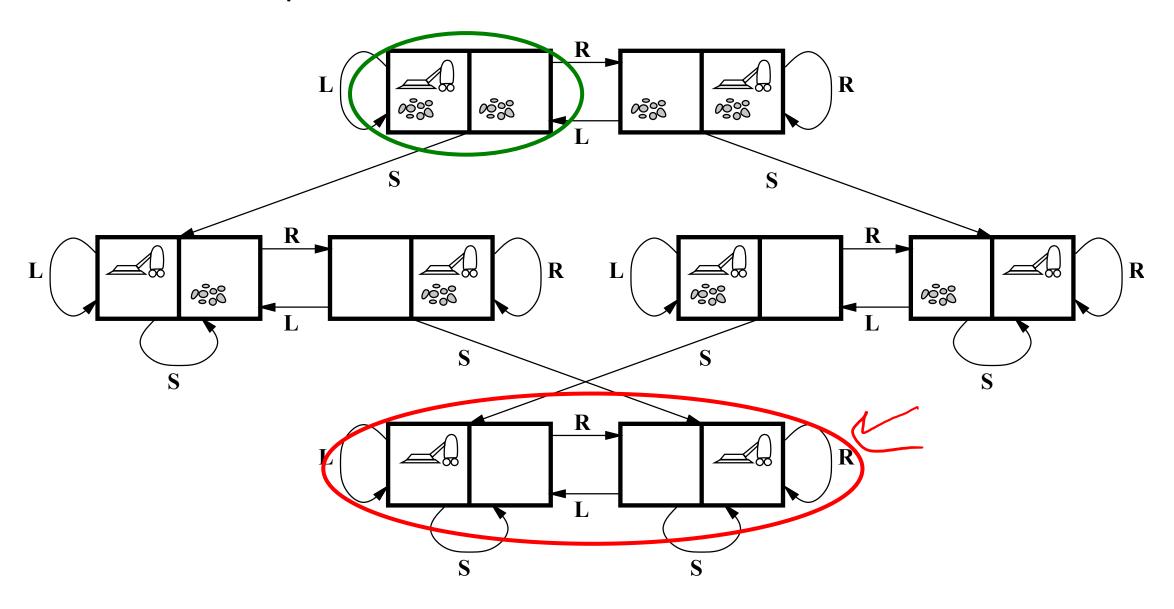

We can rarely build this full graph in memory (it's too big), but it's a useful idea

# More Examples

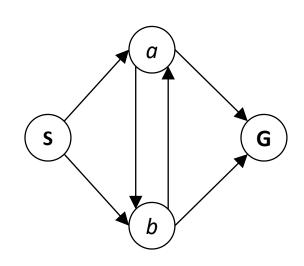

# More Examples

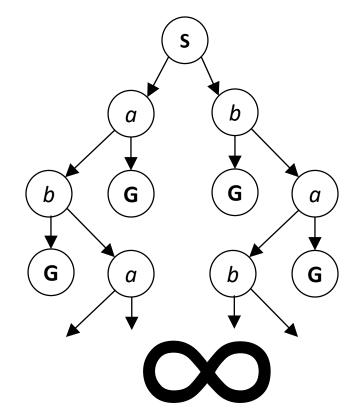

## State Space Graphs vs. Search Trees

Consider this 4-state graph:

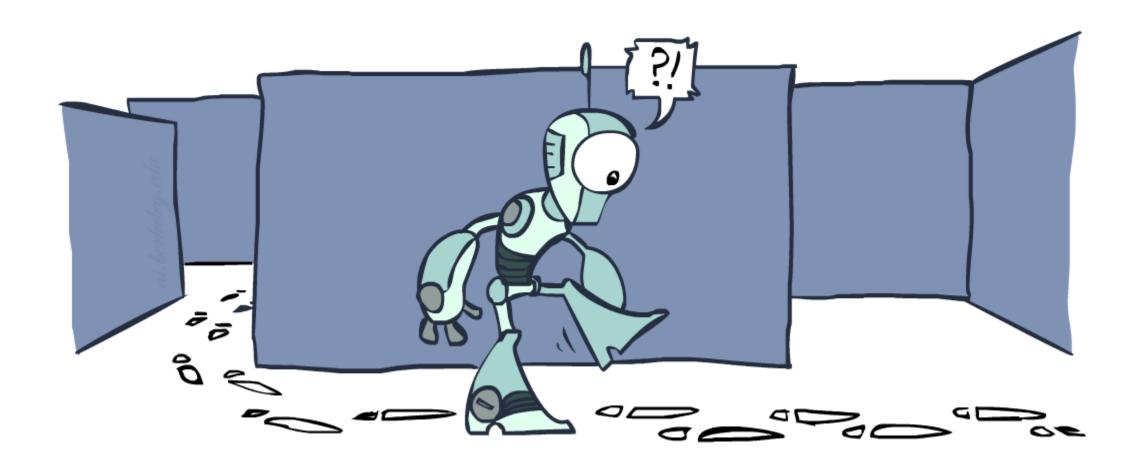

How big is its search tree (from S)?

Important: Lots of repeated structure in the search tree!

# Tree Search vs Graph Search

```
function TREE_SEARCH(problem) returns a solution, or failure
```

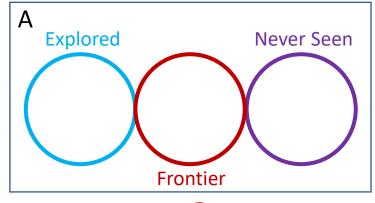

```
initialize the frontier as a specific work list (stack, queue, priority queue)
add initial state of problem to frontier
loop do
    if the frontier is empty then
         return failure
    choose a node and remove it from the frontier
    if the node contains a goal state then
         return the corresponding solution
```

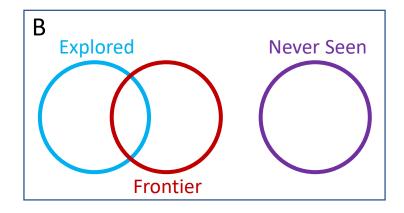

for each resulting child from node add child to the frontier

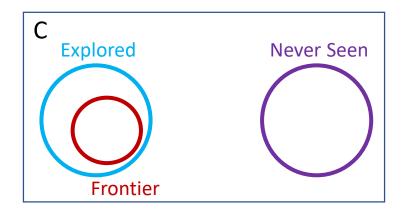

```
function GRAPH SEARCH(problem) returns a solution, or failure
   initialize the explored set to be empty
   initialize the frontier as a specific work list (stack, queue, priority queue)
   add initial state of problem to frontier
   loop do
       if the frontier is empty then
            return failure
       choose a node and remove it from the frontier
       if the node contains a goal state then
            return the corresponding solution
       add the node state to the explored set
       for each resulting child from node
           if the child state is not already in the frontier or explored set then
                add child to the frontier
```

### Piazza Poll

What is the relationship between these sets of states after each loop iteration in GRAPH\_SEARCH? (Loop invariants!!!)

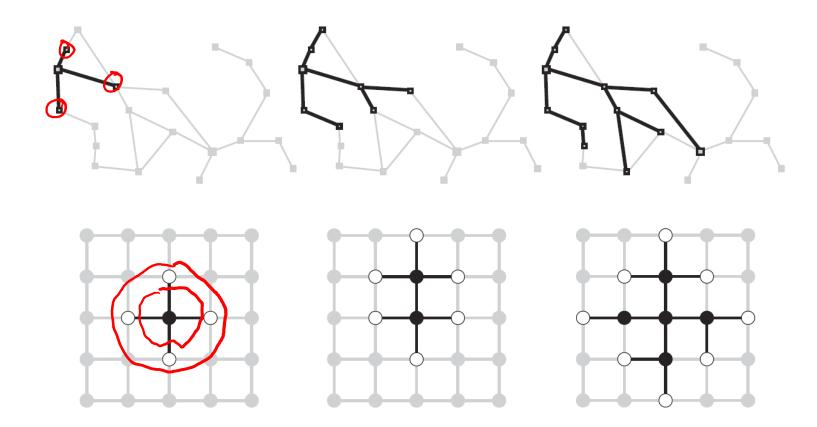

## Piazza Poll

```
function GRAPH-SEARCH(problem) returns a solution, or failure
  initialize the explored set to be empty
   initialize the frontier as a specific work list (stack, queue, priority queue)
  add initial state of problem to frontier
   loop do
       if the frontier is empty then
            return failure
       choose a node and remove it from the frontier
       if the node contains a goal state then
           return the corresponding solution
       add the node state to the explored set
       for each resulting child from node
           if the child state is not already in the frontier or explored set then
                add child to the frontier
```

## Graph Search

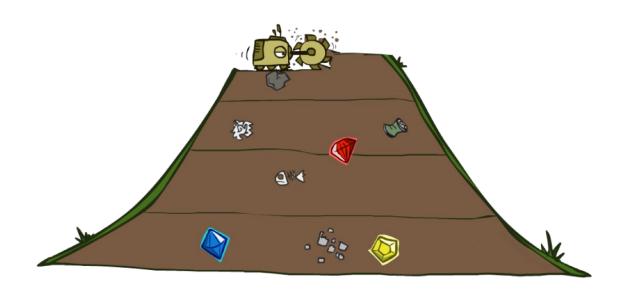

This graph search algorithm overlays a tree on a graph

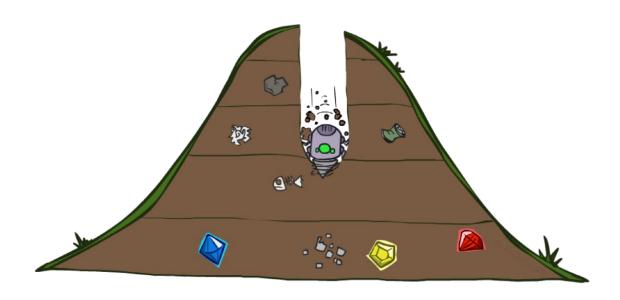

The frontier states separate the explored states from never seen states

Images: AIMA, Figure 3.8, 3.9

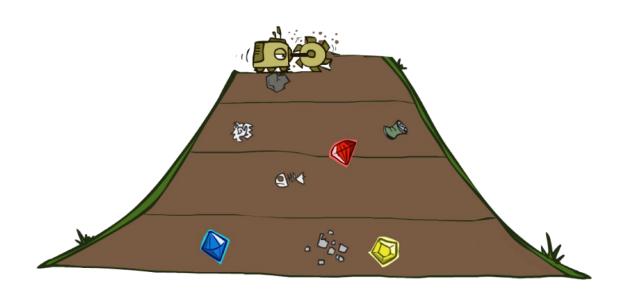

# BFS vs DFS

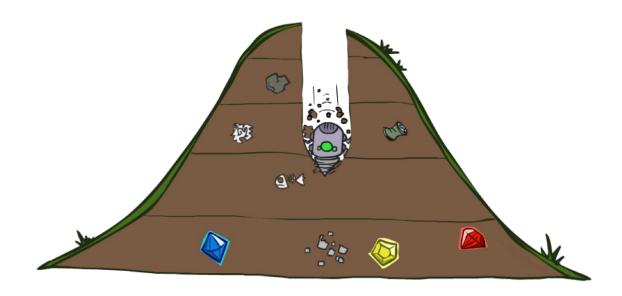

## Piazza Poll

### Is the following demo using BFS or DFS

## A Note on Implementation

### Nodes have

```
state, parent, action, path-cost
```

A child of node by action a has

```
state = result(node.state,a)
```

parent = node

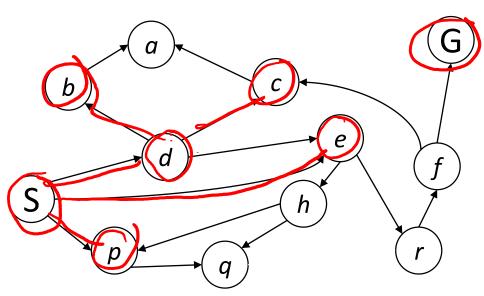

action = a

```
path-cost = node.path_cost +
    step_cost(node.state, a, self.state)
```

**PARENT** Node ACTION = RightPATH-COST = 6**S**TATE

Extract solution by tracing back parent pointers, collecting actions

# Walk-through DFS Graph Search

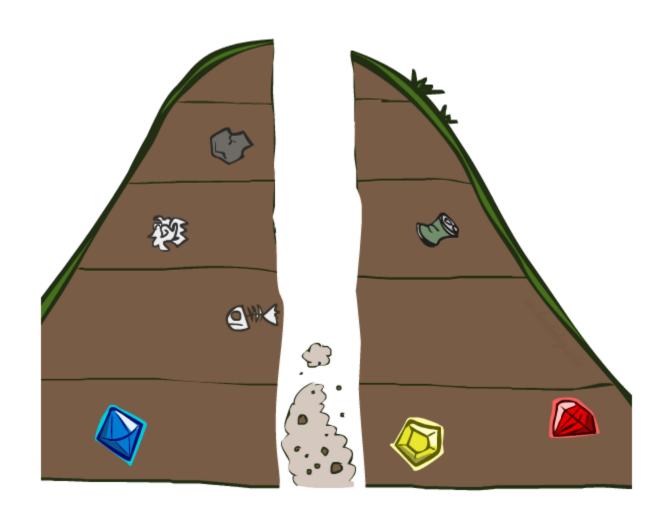

BFS vs DFS

When will BFS outperform DFS?

When will DFS outperform BFS?

## Search Algorithm Properties

### Search Algorithm Properties

Complete: Guaranteed to find a solution if one exists?

Optimal: Guaranteed to find the least cost path?

Time complexity?

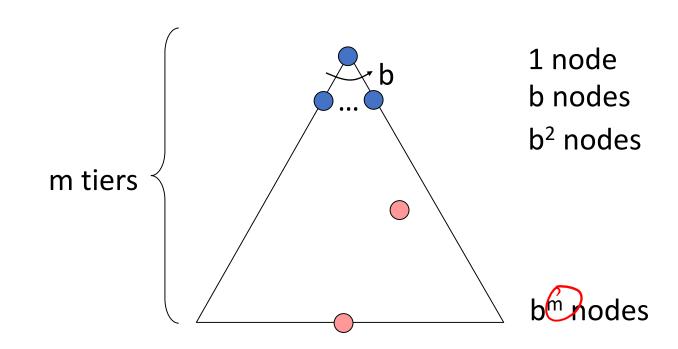

Space complexity?

#### Cartoon of search tree:

- b is the branching factor
- m is the maximum depth
- solutions at various depths

#### Number of nodes in entire tree?

■  $1 + b + b^2 + .... b^m = O(b^m)$ 

### Search Algorithm Properties

Complete: Guaranteed to find a solution if one exists?

Optimal: Guaranteed to find the least cost path?

Time complexity?

Space complexity?

#### Cartoon of search tree:

b is the branching factor

1 node b nodes b<sup>2</sup> nodes

### Piazza Poll

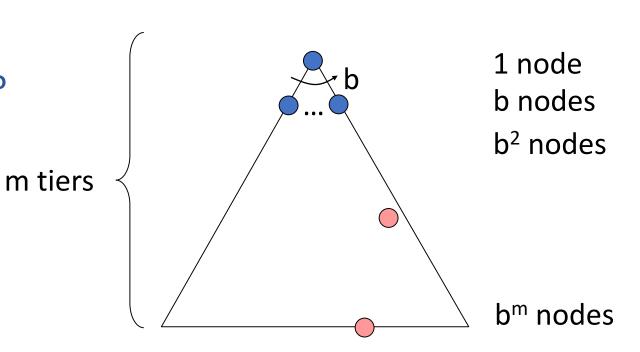

Are these the properties for BFS or DFS?

Takes O(b<sup>m</sup>) time

Uses O(bm) space on frontier

Complete with graph search

 Not optimal unless all goals are in the same level (and the same step cost everywhere)

### Depth-First Search (DFS) Properties

#### What nodes does DFS expand?

- Some left prefix of the tree.
- Could process the whole tree!
- If m is finite, takes time O(b<sup>m</sup>)

#### How much space does the frontier take?

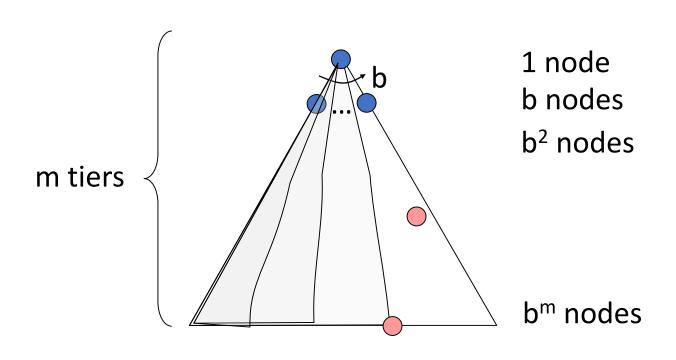

Only has siblings on path to root, so O(bm)

#### Is it complete?

m could be infinite, so only if we prevent cycles (graph search)

#### Is it optimal?

No, it finds the "leftmost" solution, regardless of depth or cost

### Breadth-First Search (BFS) Properties

#### What nodes does BFS expand?

- Processes all nodes above shallowest solution
- Let depth of shallowest solution be s
- Search takes time O(b<sup>s</sup>)

#### How much space does the frontier take?

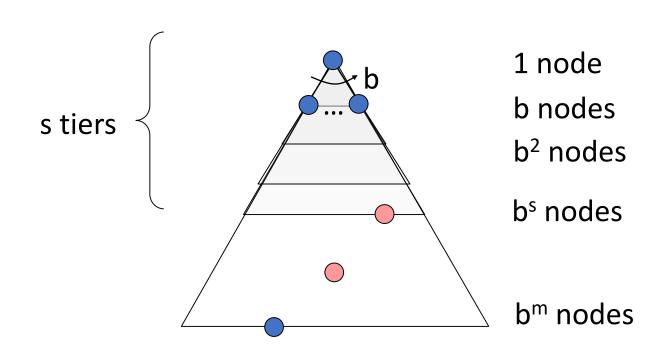

Has roughly the last tier, so O(b<sup>s</sup>)

#### Is it complete?

s must be finite if a solution exists, so yes!

#### Is it optimal?

Only if costs are all the same (more on costs later)

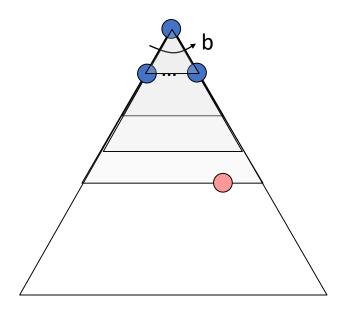

### Iterative Deepening

# Idea: get DFS's space advantage with BFS's time / shallow-solution advantages

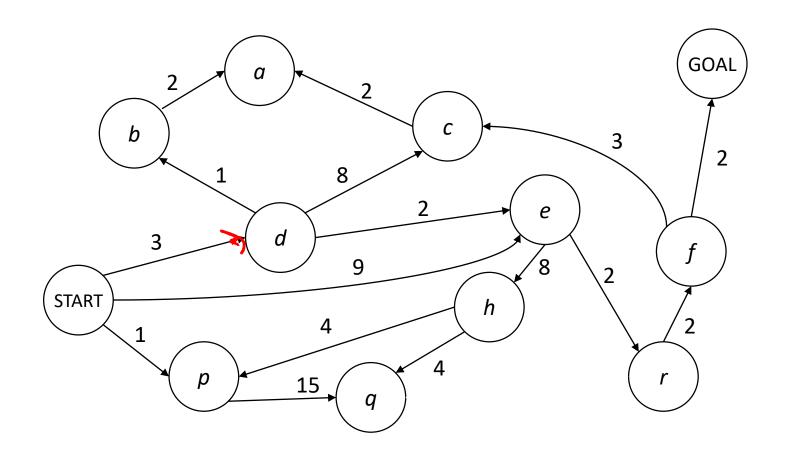

- Run a DFS with depth limit 1. If no solution...
- Run a DFS with depth limit 2. If no solution...
- Run a DFS with depth limit 3. ....

#### Isn't that wastefully redundant?

Generally most work happens in the lowest level searched, so not so bad!

# Finding a Least-Cost Path

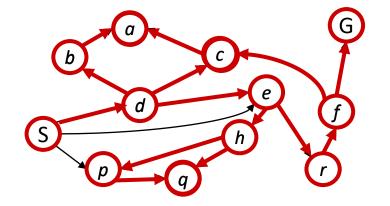

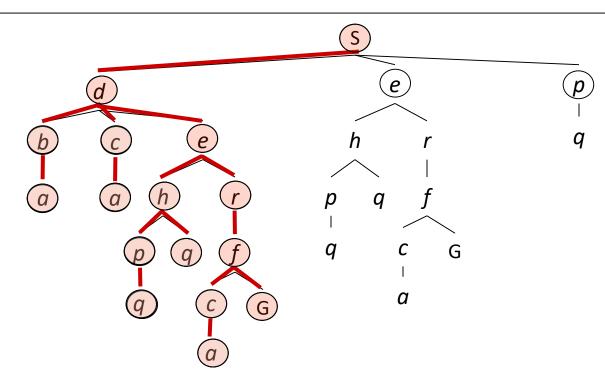

### Depth-First (Tree) Search

Strategy: expand a deepest node first

*Implementation:* 

Frontier is a LIFO stack

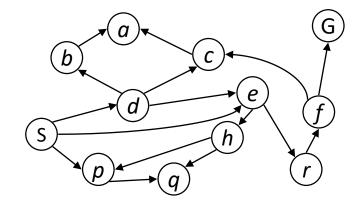

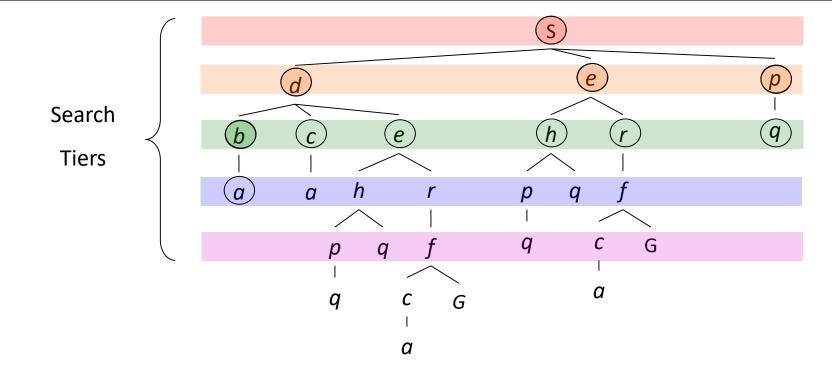

### Breadth-First (Tree) Search

Strategy: expand a shallowest node first

*Implementation:* 

Frontier is a FIFO queue

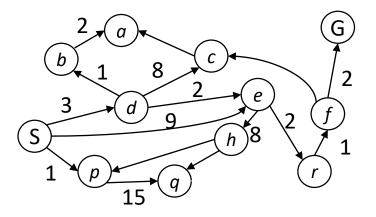

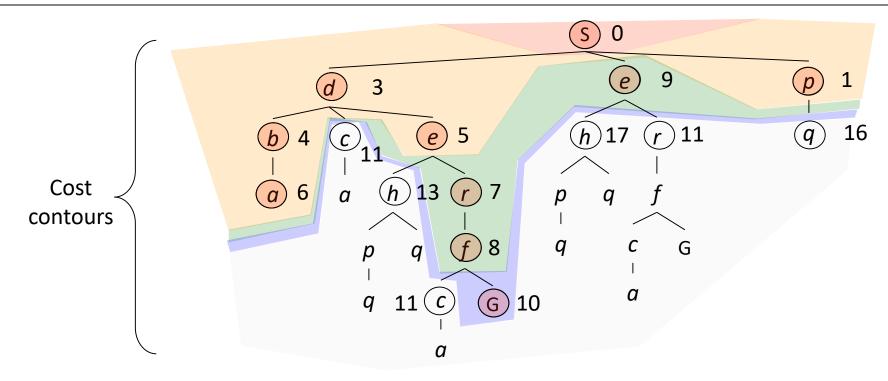

# Uniform Cost (Tree) Search

Strategy: expand a cheapest

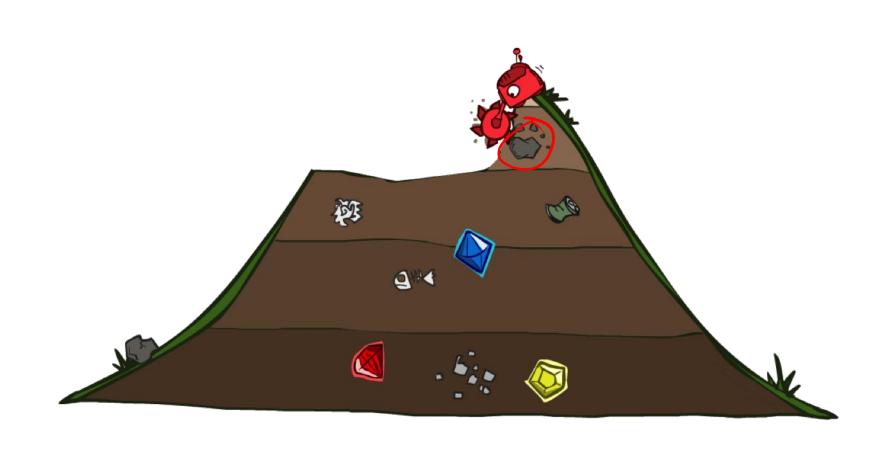

node first:

Frontier is a priority queue (priority: cumulative cost)

### Uniform Cost Search

```
function GRAPH SEARCH(problem) returns a solution, or failure
  initialize the explored set to be empty
  initialize the frontier as a specific work list (stack, queue, priority queue)
  add initial state of problem to frontier
  loop do
       if the frontier is empty then
            return failure
       choose a node and remove it from the frontier
       if the node contains a goal state then
            return the corresponding solution
       add the node state to the explored set
       for each resulting child from node
            if the child state is not already in the frontier or explored set then
                add child to the frontier
```

function UNIFORM-COST-SEARCH(problem) returns a solution, or failure initialize the explored set to be empty initialize the frontier as a priority queue using node path\_cost as the priority add initial state of problem to frontier with path\_cost = 0 loop do

return failure

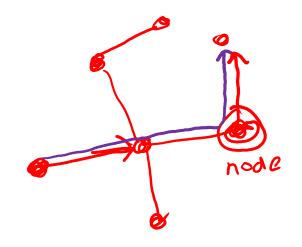

choose a node and remove it from the frontier

if the node contains a goal state then

return the corresponding solution

add the node state to the explored set

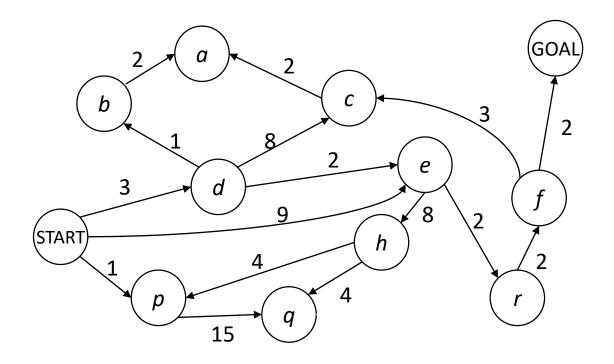

for each resulting child from node

if the child state is not already in the frontier or explored set then add child to the frontier

else if the child is already in the frontier with higher path\_cost then replace that frontier node with child

# Walk-through UCS

### Uniform Cost Search (UCS) Properties

#### What nodes does UCS expand?

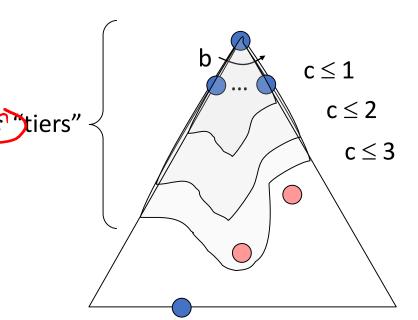

- Processes all nodes with cost less than cheapest solution!
- If that solution costs  $C^*$  and arcs cost at least  $\varepsilon$ , then the "effective depth" is roughly  $C^*/\varepsilon$
- Takes time  $O(b^{C*/\varepsilon})$  (exponential in effective depth)

#### How much space does the frontier take?

■ Has roughly the last tier, so  $O(b^{C*/\varepsilon})$ 

#### Is it complete?

Assuming best solution has a finite cost and minimum arc cost is positive, yes!

#### Is it optimal?

Yes! Proof next lecture via A\*)

### **Uniform Cost Issues**

#### Remember:

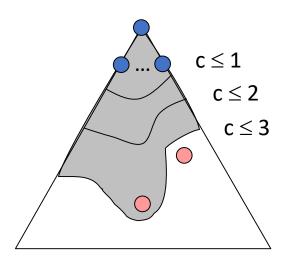

UCS explores increasing cost contours

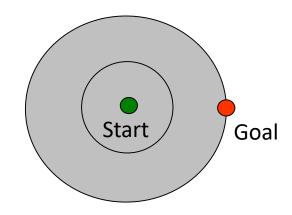

### The good:

UCS is complete and optimal!

### The bad:

- Explores options in every "direction"
- No information about goal location

We'll fix that soon!
