Key concepts from Tuesday
You can add constant-specific behavior to an enum

- Each constant can have its own override of a method
  - Don't do this unless you have to
  - If adding data is sufficient, do that instead

```java
public interface Filter {
    Image transform(Image original);
}

public enum InstagramFilter implements Filter {
    EARLYBIRD {public Image transform(Image original) { ... }},
    MAYFAIR   {public Image transform(Image original) { ... }},
    AMARO     {public Image transform(Image original) { ... }},
    RISE      {public Image transform(Image original) { ... }};
}

See Effective Java Items 34 – 38 and 42 for more information
Behavioral subtyping

Let \( q(x) \) be a property provable about objects \( x \) of type \( T \). Then \( q(y) \) should be provable for objects \( y \) of type \( S \) where \( S \) is a subtype of \( T \).

- e.g., Compiler-enforced rules in Java:
  - Subtypes can add, but not remove methods
  - Concrete class must implement all undefined methods
  - Overriding method must return same type or subtype
  - Overriding method must accept the same parameter types
  - Overriding method may not throw additional exceptions

- Also applies to specified behavior. **Subtypes must have:**
  - Same or stronger invariants
  - Same or stronger postconditions for all methods
  - Same or weaker preconditions for all methods

This is called the *Liskov Substitution Principle*. 

Barbara Liskov
This Square is not a behavioral subtype of Rectangle

class Rectangle {
    //@ invariant h>0 && w>0;
    int h, w;

    Rectangle(int h, int w) {
        this.h=h; this.w=w;
    }

    //@ requires factor > 0;
    void scale(int factor) {
        w=w*factor;
        h=h*factor;
    }

    //@ requires neww > 0;
    //@ ensures w==neww
    //@ requires neww > 0;
    //@ ensures w==neww
    void setWidth(int neww) {
        w=neww;
        h=neww;
    }
}

class Square extends Rectangle {
    //@ invariant h>0 && w>0;
    //@ invariant h==w;
    Square(int w) {
        super(w, w);
    }

    //@ requires neww > 0;
    //@ ensures w==neww
    @Override
    void setWidth(int neww) {
        w=neww;
        h=neww;
    }
}
Delegation vs. inheritance summary

• Inheritance can improve modeling flexibility
• Usually, favor composition/delegation over inheritance
  – Inheritance violates information hiding
  – Delegation supports information hiding
• Design and document for inheritance, or prohibit it
  – Document requirements for overriding any method
Note: type-casting in Java

- Sometimes you want a different type than you have
  - e.g.,
    
    ```java
double pi = 3.14;
    int indianaPi = (int) pi;
    ```

- Useful if you know you have a more specific subtype:
  - e.g.,
    ```java
    Account acct = ...;
    CheckingAccount checkingAcct =
        (CheckingAccount) acct;
    long fee = checkingAcct.getFee();
    ```
    - Will get a `ClassCastException` if types are incompatible

- Advice: avoid downcasting types
  - Never(?) downcast within superclass to a subclass
An aside: instanceof

• Operator that tests whether an object is of a given class
  
  ```java
  public void doSomething(Account acct) {
    long adj = 0;
    if (acct instanceof CheckingAccount) {
      checkingAcct = (CheckingAccount) acct;
      adj = checkingAcct.getFee();
    } else if (acct instanceof SavingsAccount) {
      savingsAcct = (SavingsAccount) acct;
      adj = savingsAcct.getInterest();
    }
    ...
  }
  ```

• Advice: avoid instanceof if possible
  – Never(?) use instanceof in a superclass to check type against subclass

Do not do this. This code is bad.
An aside: `instanceof`

- Operator that tests whether an object is of a given class

  ```java
  public void doSomething(Account acct) {
      long adj = 0;
      if (acct instanceof CheckingAccount) {
          checkingAcct = (CheckingAccount) acct;
          adj = checkingAcct.getFee();
      } else if (acct instanceof SavingsAccount) {
          savingsAcct = (SavingsAccount) acct;
          adj = savingsAcct.getInterest();
      } else if (acct instanceof InterestCheckingAccount) {
          icAccount = (InterestCheckingAccount) acct;
          adj = icAccount.getInterest();
          adj -= icAccount.getFee();
      }
  }
  ```

  Do not do this. This code is bad.
Java details: Dynamic method dispatch

1. (Compile time) Determine which class to look in
2. (Compile time) Determine method signature to be executed
   1. Find all accessible, applicable methods
   2. Select most specific matching method
Java details: Dynamic method dispatch

1. (Compile time) Determine which class to look in
2. (Compile time) Determine method signature to be executed
   1. Find all accessible, applicable methods
   2. Select most specific matching method
3. (Run time) Determine dynamic class of the receiver
4. (Run time) From dynamic class, determine method to invoke
   1. Execute method with the same signature found in step 2 (from dynamic class or one of its supertypes)
Use polymorphism to avoid instanceof

```java
public interface Account {
    ...
    public long getMonthlyAdjustment();
}

public class CheckingAccount implements Account {
    ...
    public long getMonthlyAdjustment() {
        return getFee();
    }
}

public class SavingsAccount implements Account {
    ...
    public long getMonthlyAdjustment() {
        return getInterest();
    }
}
```
Use polymorphism to avoid instanceof

```java
public void doSomething(Account acct) {
    long adj = 0;
    if (acct instanceof CheckingAccount) {
        checkingAcct = (CheckingAccount) acct;
        adj = checkingAcct.getFee();
    } else if (acct instanceof SavingsAccount) {
        savingsAcct = (SavingsAccount) acct;
        adj = savingsAcct.getInterest();
    }
    ...
}
```

Instead:

```java
public void doSomething(Account acct) {
    long adj = acct.getMonthlyAdjustment();
    ...
}
```

One design scenario

- Amazon.com processes millions of orders each year, selling in 75 countries, all 50 states, and thousands of cities worldwide. These countries, states, and cities have hundreds of distinct sales tax policies and, for any order and destination, Amazon.com must be able to compute the correct sales tax for the order and destination.
Another design scenario

- A vision processing system must detect lines in an image. For different applications the line detection requirements vary. E.g., for a vision system in a driverless car the system must process 30 images per second, but it's OK to miss some lines in some images. A face recognition system can spend 3-5 seconds analyzing an image, but requires accurate detection of subtle lines on a face.
A third design scenario

- Suppose we need to sort a list in different orders...

```java
interface Order {
    boolean lessThan(int i, int j);
}

final Order ASCENDING = (i, j) -> i < j;
final Order DESCENDING = (i, j) -> i > j;

static void sort(int[] list, Order cmp) {
    ...
    boolean mustSwap =
        cmp.lessThan(list[i], list[j]);
    ...
}
```
“Each pattern describes a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over, without ever doing it the same way twice”

Elements of a design pattern

• Name
• Abstract description of problem
• Abstract description of solution
• Analysis of consequences
Strategy pattern

• Problem: Clients need different variants of an algorithm
• Solution: Create an interface for the algorithm, with an implementing class for each variant of the algorithm
• Consequences:
  – Easily extensible for new algorithm implementations
  – Separates algorithm from client context
  – Introduces an extra interface and many classes:
    • Code can be harder to understand
    • Lots of overhead if the strategies are simple
Patterns are more than just structure

• Consider: A modern car engine is constantly monitored by a software system. The monitoring system must obtain data from many distinct engine sensors, such as an oil temperature sensor, an oxygen sensor, etc. More sensors may be added in the future.
Different patterns can have the same structure

Command pattern:

• Problem: Clients need to execute some (possibly flexible) operation without knowing the details of the operation

• Solution: Create an interface for the operation, with a class (or classes) that actually executes the operation

• Consequences:
  – Separates operation from client context
  – Can specify, queue, and execute commands at different times
  – Introduces an extra interface and classes:
    • Code can be harder to understand
    • Lots of overhead if the commands are simple
Design pattern conclusions

• Provide shared language
• Convey shared experience
• Can be system and language specific

One design scenario

- A GUI-based document editor works with multiple document formats. Some parts of the algorithm to load a document (e.g., reading a file, rendering to the screen) are the same for all document formats, and other parts of the algorithm vary from format-to-format (e.g. parsing the file input).
Another design scenario

- Several versions of a domain-specific machine learning algorithm are being implemented to use data stored in several different database systems. The basic algorithm for all versions is the same; just the interactions with the database are different from version to version.
The abstract java.util.AbstractList<E>

abstract T get(int i);
abstract int size();
boolean set(int i, E e); // pseudo-abstract
boolean add(E e); // pseudo-abstract
boolean remove(E e); // pseudo-abstract
boolean addAll(Collection<? extends E> c);
boolean removeAll(Collection<?> c);
boolean retainAll(Collection<?> c);
boolean contains(E e);
boolean containsAll(Collection<?> c);
void clear();
boolean isEmpty();
abstract Iterator<E> iterator();
Object[] toArray()
<T> T[] toArray(T[] a);
...
Template method pattern

• Problem: An algorithm consists of customizable parts and invariant parts

• Solution: Implement the invariant parts of the algorithm in an abstract class, with abstract (unimplemented) primitive operations representing the customizable parts of the algorithm. Subclasses customize the primitive operations

• Consequences
  – Code reuse for the invariant parts of algorithm
  – Customization is restricted to the primitive operations
  – Inverted (Hollywood-style) control for customization
Template method vs. the strategy pattern

- **Template method uses inheritance to vary part of an algorithm**
  - Template method implemented in supertype, primitive operations implemented in subtypes
- **Strategy pattern uses delegation to vary the entire algorithm**
  - Strategy objects are reusable across multiple classes
  - Multiple strategy objects are possible per class
Summary

• Use UML class diagrams to simplify communication
• Design patterns...
  – Convey shared experience, general solutions
  – Facilitate communication
• Specific design patterns for reuse:
  – Strategy
  – Template method
  – Iterator
