Machine Learning – 10701/15781

Carlos Guestrin

Carnegie Mellon University

January 25th, 2006

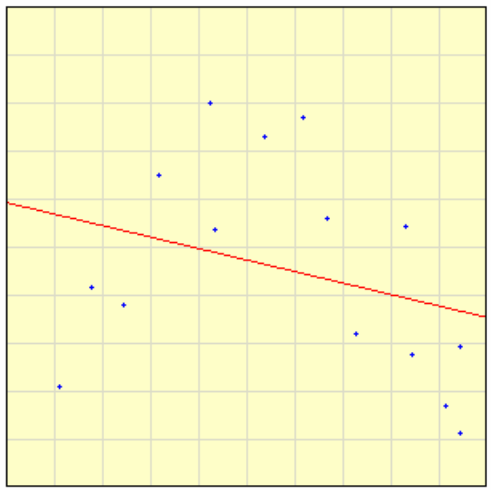
Announcements

- Recitations stay on Thursdays
  - 5-6:30pm in Wean 5409
- Special Matlab recitation:
  - Jan. 25 Wed. 5:00-7:00pm in NSH 3305
- First homework is out:
  - Programming part and Analytic part
  - Remember collaboration policy: can discuss questions, but need to write your own solutions and code
  - Due Mon. Feb 6th **beginning of class**
  - Start early!

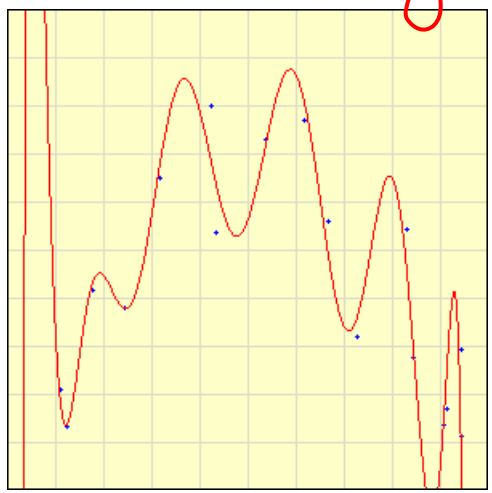
Bias-Variance Tradeoff

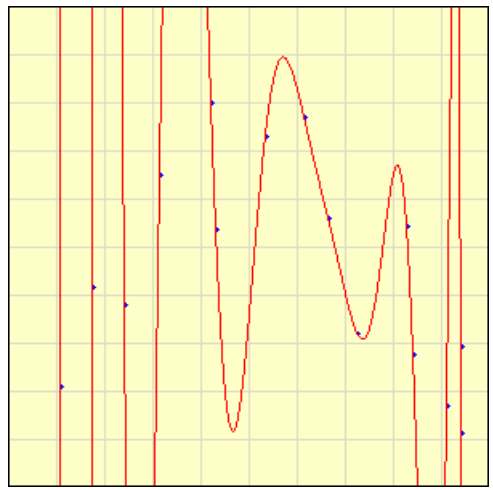
- Choice of hypothesis class introduces learning bias
  - More complex class → less bias
  - More complex class → more variance

biased solution



high variance solution





Training set error

$$\mathbf{w}^* = \arg\min_{\mathbf{w}} \sum_{j=1}^{\text{size Dataset}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

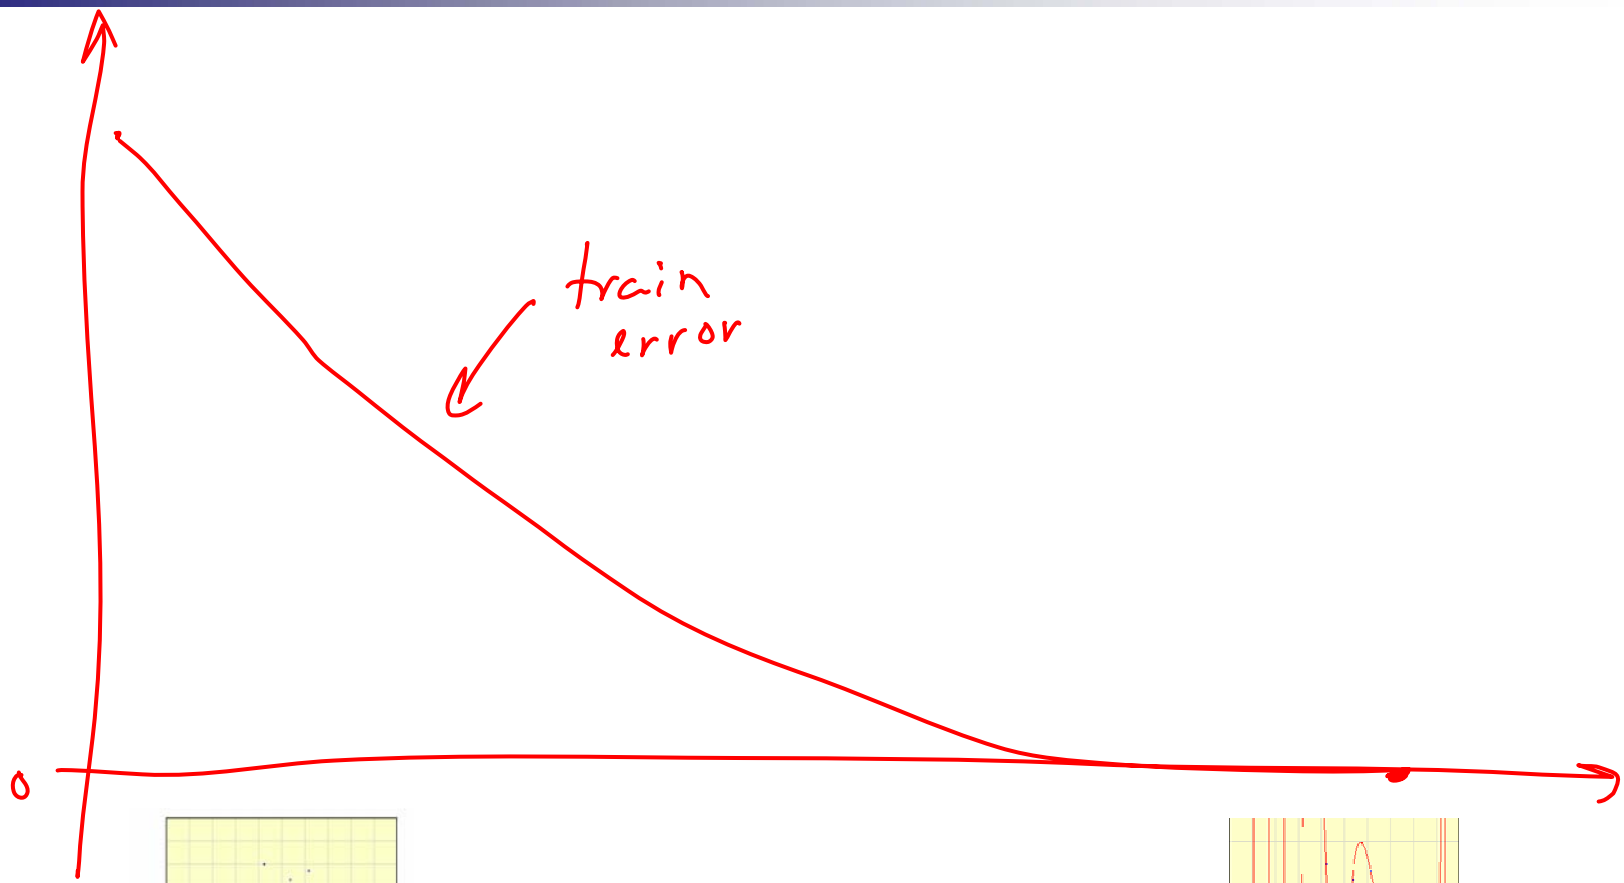
- Given a dataset (Training data)
- Choose a loss function
  - e.g., squared error (L_2) for regression
- **Training set error:** For a particular set of parameters, loss function on training data:

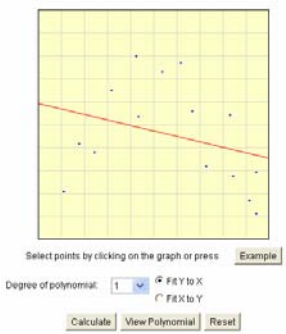
$$error_{train}(\mathbf{w}) = \frac{1}{N_{train}} \sum_{j=1}^{N_{train}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

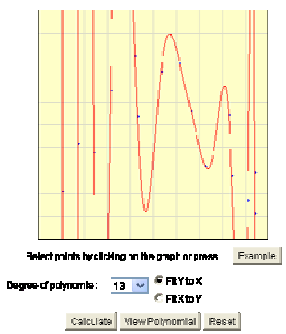
$$w^* = \arg\min_w \; error_{train}(w)$$

Training set error as a function of model complexity

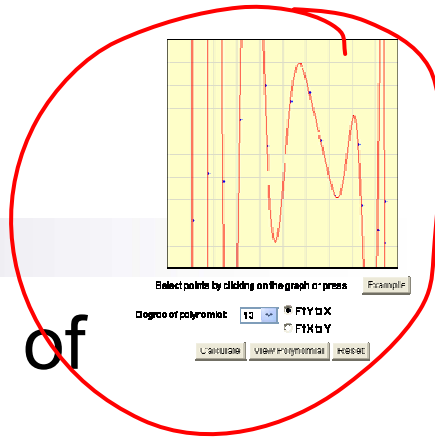
$$error_{train}(\mathbf{w}) = \frac{1}{N_{train}} \sum_{j=1}^{N_{train}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$







Prediction error



- Training set error can be poor measure of "quality" of solution
- **Prediction error:** We really care about error over all possible input points, not just training data:

$$error_{true}(\mathbf{w}) = E_{\mathbf{x}}\left[\left(t(\mathbf{x}) - \sum_i w_i h_i(\mathbf{x})\right)^2\right]$$

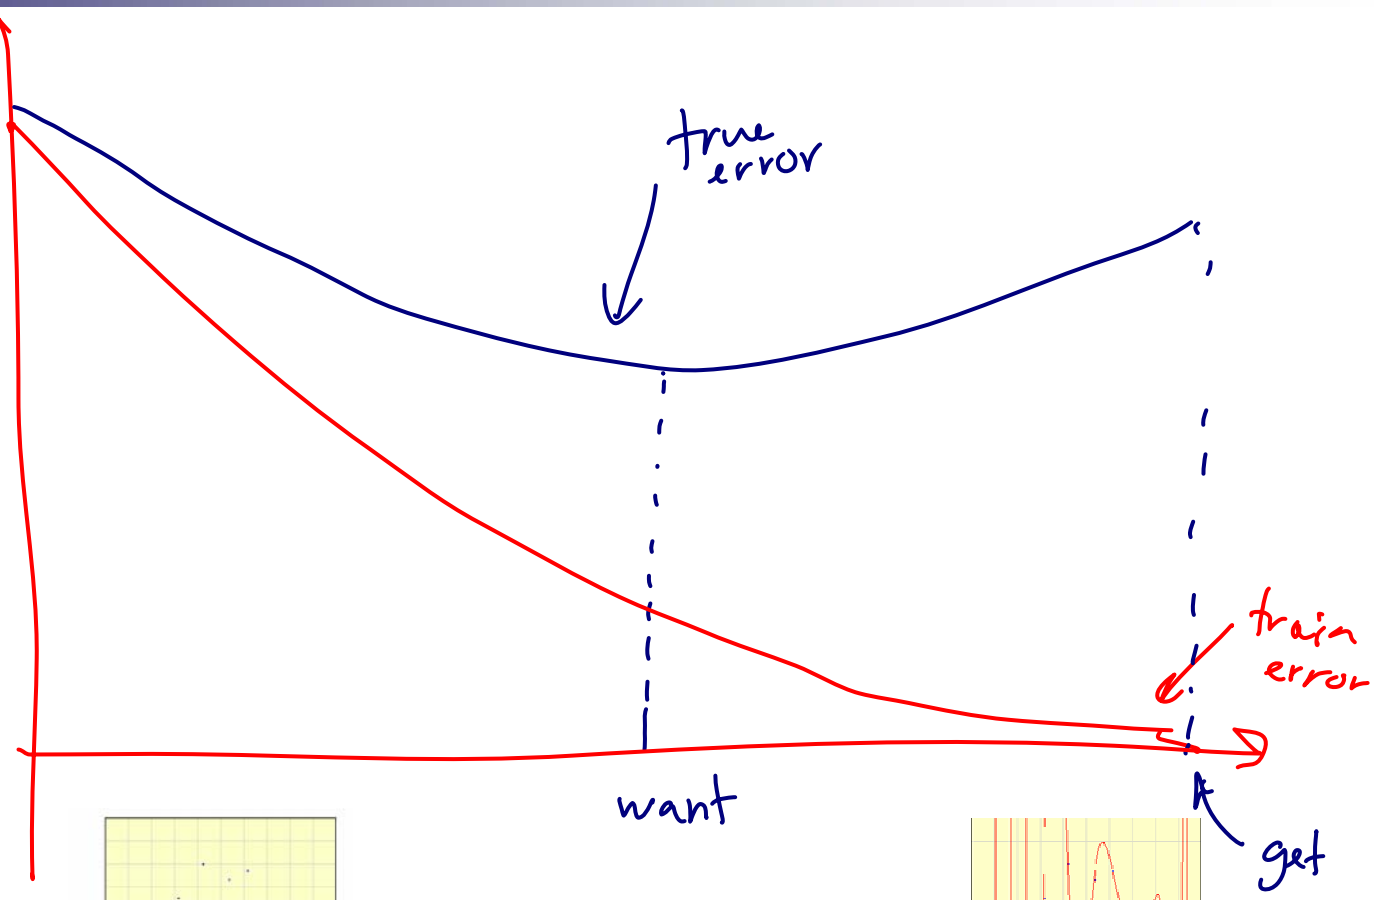
$$= \int_{\mathbf{x}} \left(t(\mathbf{x}) - \sum_i w_i h_i(\mathbf{x})\right)^2 p(\mathbf{x}) d\mathbf{x}$$

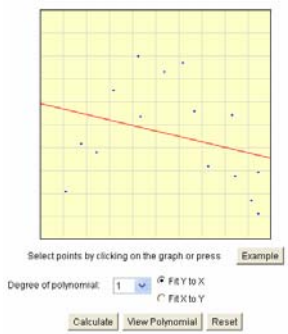
over possible inputs

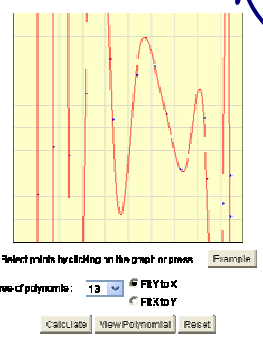
Prediction error as a function of model complexity

$$error_{train}(\mathbf{w}) = \frac{1}{N_{train}} \sum_{j=1}^{N_{train}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

$$error_{true}(\mathbf{w}) = \int_{\mathbf{x}} \left(t(\mathbf{x}) - \sum_i w_i h_i(\mathbf{x}) \right)^2 d\mathbf{x}$$







Computing prediction error

- Computing prediction
  - hard integral
  - May not know t(**x**) for every **x**

$$error_{true}(\mathbf{w}) = \int_{\mathbf{x}} \left(t(\mathbf{x}) - \sum_i w_i h_i(\mathbf{x}) \right)^2 d\mathbf{x}$$

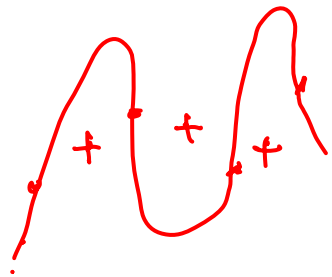
- Monte Carlo integration (sampling approximation)
  - Sample a set of i.i.d. points $\{\mathbf{x}_1,\ldots,\mathbf{x}_M\}$ from p(**x**)
  - Approximate integral with sample average

$$error_{true}(\mathbf{w}) \approx \frac{1}{M} \sum_{j=1}^{M} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

Why training set error doesn't approximate prediction error?

- Sampling approximation of prediction error:

$$error_{true}(\mathbf{w}) \approx \frac{1}{M}\sum_{j=1}^{M}\left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j)\right)^2$$



- Training error :

$$error_{train}(\mathbf{w}) = \frac{1}{N_{train}}\sum_{j=1}^{N_{train}}\left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j)\right)^2$$

- Very similar equations!!!
  - Why is training set a bad measure of prediction error???

Why training set error doesn't approximate prediction error?

Because you cheated!!!

Training error good estimate for a single **w,**
But you optimized **w** with respect to the training error,
and found **w** that is good for this set of samples

Training error is a (optimistically) biased estimate of prediction error

- Very similar equations!!!
  - Why is training set a bad measure of prediction error???

Test set error

$$\mathbf{w}^* = \arg\min_{\mathbf{w}} \sum_j \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

- Given a dataset, **randomly** split it into two parts:
  - Training data – $\{\mathbf{x}_1, \ldots, \mathbf{x}_{Ntrain}\}$
  - Test data – $\{\mathbf{x}_1, \ldots, \mathbf{x}_{Ntest}\}$
- Use training data to optimize parameters **w**
- **Test set error:** For the ***final solution*** **w***, evaluate the error using:

only here

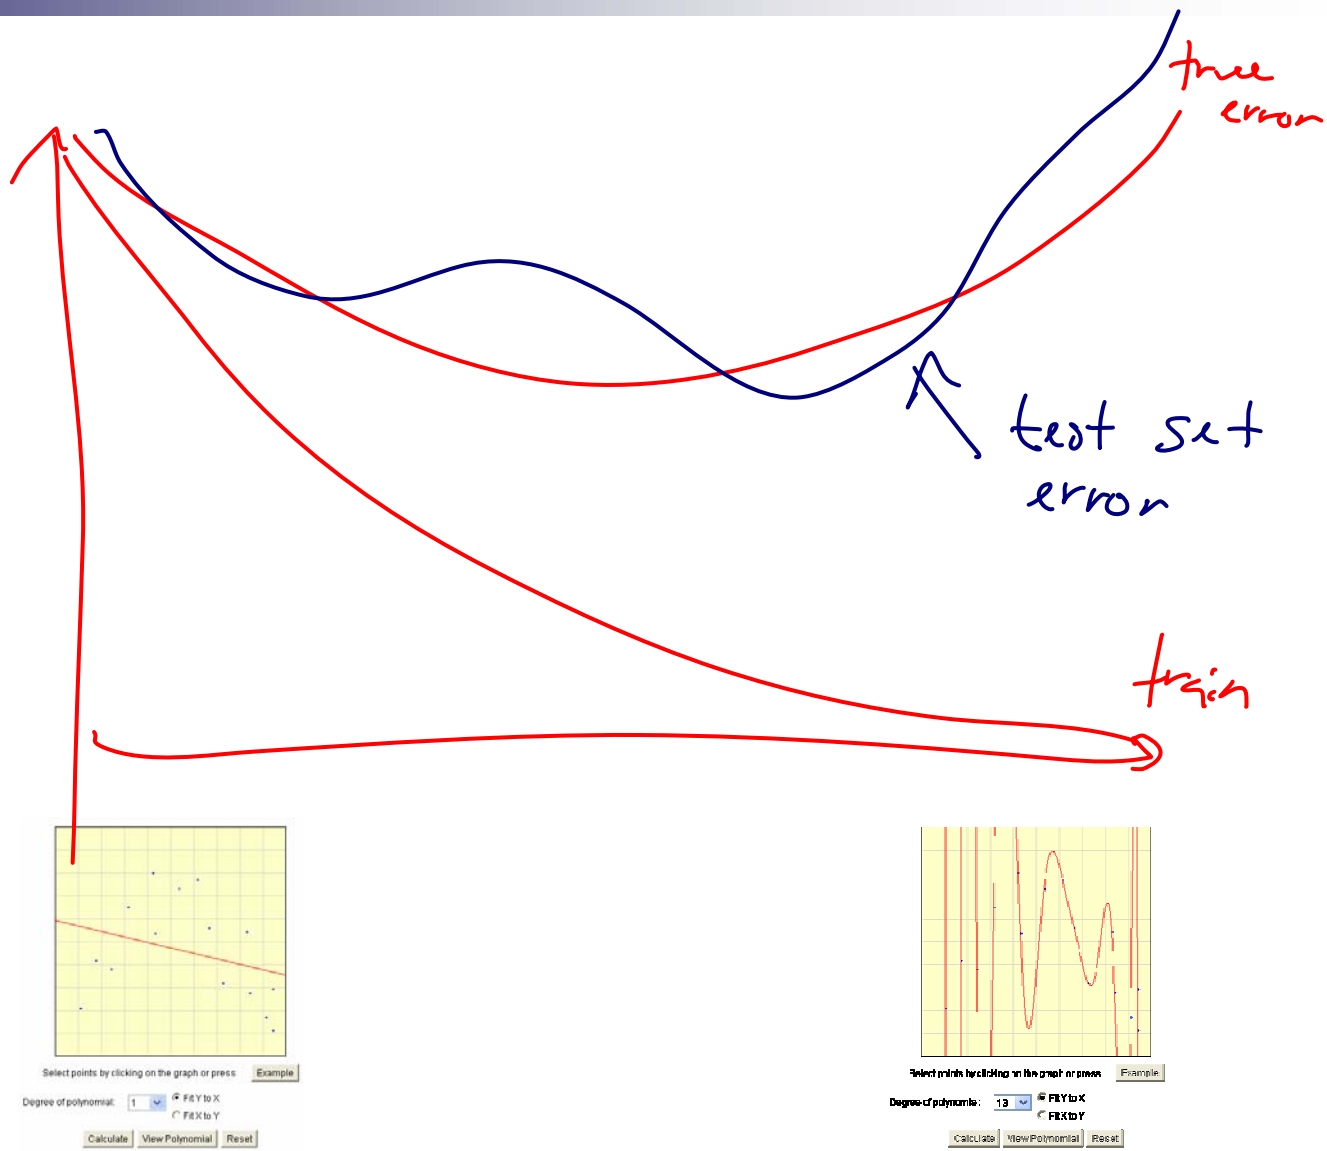
$$error_{test}(\mathbf{w}^*) = \frac{1}{N_{test}} \sum_{j=1}^{N_{test}} \left(t(\mathbf{x}_j) - \sum_i w_i^* h_i(\mathbf{x}_j) \right)^2$$

Test set error as a function of model complexity

$$error_{train}(\mathbf{w}) = \frac{1}{N_{train}} \sum_{j=1}^{N_{train}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

$$error_{true}(\mathbf{w}) = \int_{\mathbf{x}} \left(t(\mathbf{x}) - \sum_i w_i h_i(\mathbf{x}) \right)^2 p(\mathbf{x}) d\mathbf{x}$$

$$error_{test}(\mathbf{w}) = \frac{1}{N_{test}} \sum_{j=1}^{N_{test}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$



How many points to I use for training/testing?

- Very hard question to answer!
  - Too few training points, learned **w** is bad
  - Too few test points, you never know if you reached a good solution
- Bounds, such as Hoeffding's inequality can help:

$$P(|\ \hat{\theta} - \theta^*\ | \geq \epsilon) \quad \leq \quad 2e^{-2N\epsilon^2}$$

sample average error — true error

- More on this later this semester, but still hard to answer
- Typically:
  - if you have a reasonable amount of data, pick test set "large enough" for a "reasonable" estimate of error, and use the rest for learning
  - if you have little data, then you need to pull out the big guns…
    - e.g., bootstrapping

Error estimators

$$error_{true}(\mathbf{w}) = \int_{\mathbf{x}} \left(t(\mathbf{x}) - \sum_i w_i h_i(\mathbf{x}) \right)^2 p(x) d\mathbf{x}$$

← true gold standard

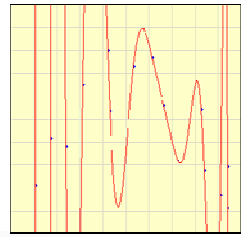
$$error_{train}(\mathbf{w}) = \frac{1}{N_{train}} \sum_{j=1}^{N_{train}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

← optimistically biased

$$error_{test}(\mathbf{w}) = \frac{1}{N_{test}} \sum_{j=1}^{N_{test}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

← unbiased, but has variance

Error as a function of number of training examples for a fixed model complexity



$$error_{train}(\mathbf{w}) = \frac{1}{N_{train}} \sum_{j=1}^{N_{train}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

$$error_{test}(\mathbf{w}) = \frac{1}{N_{test}} \sum_{j=1}^{N_{test}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

little data

infinite data

Error estimators

Be careful!!!

Test set only unbiased if you never never never never do any any any any learning on the test data

For example, if you use the test set to select the degree of the polynomial… no longer unbiased!!!
(We will address this problem later in the semester)

$$error_{test}(\mathbf{w}) = \frac{1}{N_{test}} \sum_{j=1}^{N_{test}} \left(t(\mathbf{x}_j) - \sum_i w_i h_i(\mathbf{x}_j) \right)^2$$

6 Cross validation

Overfitting

- **Overfitting:** a learning algorithm overfits the training data if it outputs a solution **w** when there exists another solution **w'** such that:

$$[error_{train}(\mathbf{w}) < error_{train}(\mathbf{w}')] \wedge [error_{true}(\mathbf{w}') < error_{true}(\mathbf{w})]$$

What's (supervised) learning, more formally

- Given:
  - **Dataset**: Instances $\{\langle \mathbf{x}_1; t(\mathbf{x}_1)\rangle, \ldots, \langle \mathbf{x}_N; t(\mathbf{x}_N)\rangle\}$
    - e.g., $\langle \mathbf{x}_i; t(\mathbf{x}_i)\rangle$ = ⟨(GPA=3.9,IQ=120,MLscore=99);150K⟩
  - **Hypothesis space**: *H*
    - e.g., polynomials of degree 8 $w_0 + w_1 x + w_2 x^2 \ldots$
  - **Loss function**: measures quality of hypothesis $h \in H$
    - e.g., squared error for regression
- Obtain:
  - **Learning algorithm**: obtain $h \in H$ that minimizes loss function
    - e.g., using matrix operations for regression
    - Want to minimize prediction error, but can only minimize error in dataset

↳ train error

Types of (supervised) learning problems, revisited

- **Regression**, e.g.,
  - **dataset**: ⟨position; temperature⟩
  - **hypothesis space**: polynomials degree 8
  - **Loss function**: squared loss
- **Density estimation**, e.g.,
  - **dataset**: ⟨grades⟩ → 75, 85, 99, 99, 99, ...
  - **hypothesis space**: Gaussian
  - **Loss function**: MLE, MAP, ...
- **Classification**, e.g.,
  - **dataset**: ⟨brain image; {verb v. noun}⟩
  - **hypothesis space**: a little more complicated
  - **Loss function**: 0/1 loss → $error(h,x) = \begin{cases} 1 & \text{if } h(x) \neq t(x) \\ 0 & \text{if } h(x) = t(x) \end{cases}$

Learning is (simply) function approximation!

- The general (supervised) learning problem:
  - Given some data (including features), hypothesis space, loss function
  - Learning is no magic!
  - Simply trying to find a function that fits the data
- **Regression** $h: \mathbb{R}^d \rightarrow \mathbb{R}$
- **Density estimation** $h: X \rightarrow [0,1]$
- **Classification** $h: X \rightarrow \{y_1, y_2, y_3, \ldots, y_K\}$
- (Not surprisingly) Seemly different problem, very similar solutions…

Classification

- **Learn**: h:**X** $\mapsto$ Y
  - **X** – features
  - Y – target classes = {true, false}, {A, B, C}, ...

- Suppose you know P(Y|**X**) exactly, how should you classify?
  - Bayes classifier:

$$y^* = h_{Bayes}(x) = \arg\max_y P(Y=y \mid X=x)$$

- **Why?**

Optimal classification

Solve classification by learning $P(Y|X)$

- **Theorem:** Bayes classifier h_{Bayes} is optimal!

if you know $P(X|X)$ exactly

$$y^* = h_{Bayes}(x) = \underset{y}{\operatorname{argmax}}\ P(Y=y \mid X=x)$$

- That is $error_{true}(h_{Bayes})) \leq error_{true}(h),\ \forall h(\mathbf{x})$
- **Proof**:

using 0/1 loss

want to minimize

$$P(error) = \int_X p(error, x)\, dx = \int_X P(error|x) \cdot p(x)\, dx$$

↳ minimize $P(error)$ by minimizing $P(error|x)$ $\forall x$

$$P(error|x) = \begin{cases} P(Y=t|x) = 0.2 ; & h(x)=f \\ P(Y=f|x) = 0.8 ; & h(x)=t \end{cases}$$

Bayes Rule

likelihood prior

$$P(Y|X) = \frac{P(X|Y)P(Y)}{P(X)}$$

want

Which is shorthand for:

$$(\forall i, j) P(Y = y_i | X = x_j) = \frac{P(X = x_j | Y = y_i) P(Y = y_i)}{P(X = x_j)}$$

particular class particular features normalization

$$\arg\max_y \frac{P(X=x|Y=y)P(Y=y)}{P(X)} = \arg\max_y P(x|y) \cdot P(y)$$

How hard is it to learn the optimal classifier?

- Data =

Sky	Temp	Humid	Wind	Water	Forecst	EnjoySpt
Sunny	Warm	Normal	Strong	Warm	Same	Yes
Sunny	Warm	High	Strong	Warm	Same	Yes
Rainy	Cold	High	Strong	Warm	Change	No
Sunny	Warm	High	Strong	Cool	Change	Yes

- How do we represent these? How many parameters?
  - Prior, P(Y):
    - Suppose Y is composed of *k* classes

P(Y)

A	B	C	D
0.4	0.4	0.15	0.05

K-1 parameters

  - Likelihood, P(**X**|Y):
    - Suppose **X** is composed of *n* binary features

P(X|Y): for each Y=y

x_1 / x_2	t	f
t	0.8	0.1
f	0.1	0

$P(X|Y=y) \leftarrow 2^n - 1$ parameters

$P(X|Y) \leftarrow K(2^n - 1)$ "

- Complex model → High variance with limited data!!!

Conditional Independence

- X is **conditionally independent** of Y given Z, if the probability distribution governing X is independent of the value of Y, given the value of Z

$$(\forall i, j, k) P(X = i | Y = j, Z = k) = P(X = i | Z = k)$$

- e.g., $P(Thunder | Rain, Lightning) = P(Thunder | Lightning)$

Conditioned on L, T & R are indep.

- Equivalent to:

$$P(X, Y \mid Z) = P(X \mid Z) P(Y \mid Z)$$

What if features are independent?

- Predict 10701Grade (Final)
- From two **conditionally Independent** features
  - HomeworkGrade
  - ClassAttendance

$P(F \mid HC) \propto \underbrace{P(HC \mid F)}_{\text{harder to estimate}} \cdot P(F)$

cond. indep: $P(HC \mid F) = P(H \mid F)\, P(C \mid F)$

$P(F \mid HC) = P(F)\, \underbrace{P(H \mid F)\, P(C \mid F)}_{\text{easier to estimate}}$

The Naïve Bayes assumption

- Naïve Bayes assumption:
  - Features are independent given class:

$$P(X_1, X_2|Y) = P(X_1|X_2, Y)P(X_2|Y)$$
$$= P(X_1|Y)P(X_2|Y)$$

  - More generally:

$$P(X_1 \ldots X_n|Y) = \prod_i P(X_i|Y)$$

- How many parameters now?
  - Suppose **X** is composed of *n* binary features

$P(X_i|Y) = K(2-1)$; $P(X|Y) = nK$

The Naïve Bayes Classifier

- Given:
  - Prior P(Y)
  - *n* conditionally independent features **X** given the class Y
  - For each X_i, we have likelihood $P(X_i|Y)$

- Decision rule:

$$y^* = h_{NB}(\mathbf{x}) = \arg\max_y P(y) P(x_1, \ldots, x_n \mid y)$$
$$= \arg\max_y P(y) \prod_i P(x_i|y)$$

- If assumption holds, NB is optimal classifier!

because $P(y) \prod P(x_i|y) \propto P(y|x)$

MLE for the parameters of NB

- Given dataset
  - Count(A=a,B=b) ← number of examples where A=a and B=b

- MLE for NB, simply:
  - Prior: $P(Y=y) = \frac{Count(Y=y)}{N}$
  - Likelihood: $P(X_i=x_i|Y_i=y_i) = \frac{Count(X_i=x_i, Y_i=y_i)}{Count(Y_i=y_i)}$

Subtleties of NB classifier 1 – Violating the NB assumption

- Usually, features are not conditionally independent:

$$P(X_1 \ldots X_n | Y) \neq \prod_i P(X_i | Y)$$

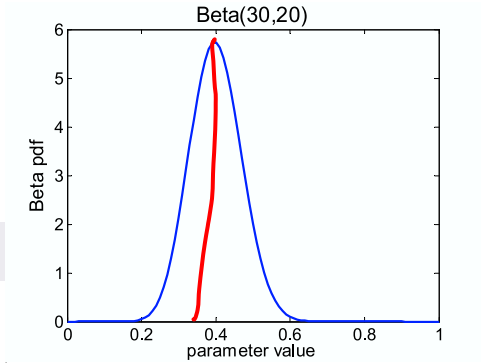
- Actual probabilities P(Y|**X**) often biased towards 0 or 1
- Nonetheless, NB is the single most used classifier out there
  - NB often performs well, even when assumption is violated
  - [Domingos & Pazzani ’96] discuss some conditions for good performance

Subtleties of NB classifier 2 – Insufficient training data

- What if you never see a training instance where X_1=a when Y=b?
  - e.g., Y={SpamEmail}, X_1={'Enlargement'}
  - $P(X_1=a \mid Y=b) = 0$
- Thus, no matter what the values $X_2,\ldots,X_n$ take:
  - $P(Y=b \mid X_1=a,X_2,\ldots,X_n) = 0$

- What now???

MAP for Beta distribution



multinomial-like

$$P(\theta \mid \mathcal{D}) = \frac{\theta^{\beta_H+\alpha_H-1}(1-\theta)^{\beta_T+\alpha_T-1}}{B(\beta_H+\alpha_H, \beta_T+\alpha_T)} \sim Beta(\beta_H+\alpha_H, \beta_T+\alpha_T)$$

$\alpha_H = 3$
$\alpha_T = 2$
β_H, β_T extra data

- MAP: use most likely parameter:

$$\hat{\theta} = \arg\max_{\theta} P(\theta \mid \mathcal{D}) = \frac{\beta_H+\alpha_H-1}{\beta_H+\alpha_H+\beta_T+\alpha_T-2}$$

- Beta prior equivalent to extra thumbtack flips
- As $N \rightarrow \infty$, prior is "forgotten"
- **But, for small sample size, prior is important!**

Bayesian learning for NB parameters – a.k.a. smoothing

- Dataset of *N* examples
- Prior
  - "distribution" $Q(X_i,Y)$, $Q(Y)$
  - *m* "virtual" examples
- MAP estimate
  - $P(X_i|Y)$
- Now, even if you never observe a feature/class, posterior probability never zero

Text classification

- Classify e-mails
  - Y = {Spam,NotSpam}
- Classify news articles
  - Y = {what is the topic of the article?}
- Classify webpages
  - Y = {Student, professor, project, …}

- What about the features **X**?
  - The text!

Features **X** are entire document – X_i for i^{th} word in article

I can only comment on the Kings, but the most
obvious candidate for pleasant surprise is Alex
Zhitnik. He came highly touted as a defensive
defenseman, but he's clearly much more than that.
Great skater and hard shot (though wish he were
more accurate). In fact, he pretty much allowed
the Kings to trade away that huge defensive
liability Paul Coffey. Kelly Hrudey is only the
biggest disappointment if you thought he was any
good to begin with. But, at best, he's only a
mediocre goaltender. A better choice would be
Tomas Sandstrom, though not through any fault of
his own, but because some thugs in Toronto decided
```

NB for Text classification

- P(**X**|Y) is huge!!!
  - Article at least 1000 words, **X**={X_1,…,X_{1000}}
  - X_i represents i^{th} word in document, i.e., the domain of X_i is entire vocabulary, e.g., Webster Dictionary (or more), 10,000 words, etc.

- NB assumption helps a lot!!!
  - P(X_i=x_i|Y=y) is just the probability of observing word x_i in a document on topic y

$$h_{NB}(\mathbf{x}) = \arg\max_y P(y) \prod_{i=1}^{LengthDoc} P(x_i|y)$$

Bag of words model

- Typical additional assumption – **Position in document doesn't matter**: $P(X_i=x_i|Y=y) = P(X_k=x_i|Y=y)$
  - "Bag of words" model – order of words on the page ignored
  - Sounds really silly, but often works very well!

$$P(y) \prod_{i=1}^{LengthDoc} P(x_i|y)$$

When the lecture is over, remember to wake up the person sitting next to you in the lecture room.

Bag of words model

NB with Bag of Words for text classification

- Learning phase:
  - Prior P(Y)
    - Count how many documents you have from each topic (+ prior)
  - $P(X_i|Y)$
    - For each topic, count how many times you saw word in documents of this topic (+ prior)
- Test phase:
  - For each document
    - Use naïve Bayes decision rule

$$h_{NB}(\mathbf{x}) = \arg\max_y P(y) \prod_{i=1}^{LengthDoc} P(x_i|y)$$

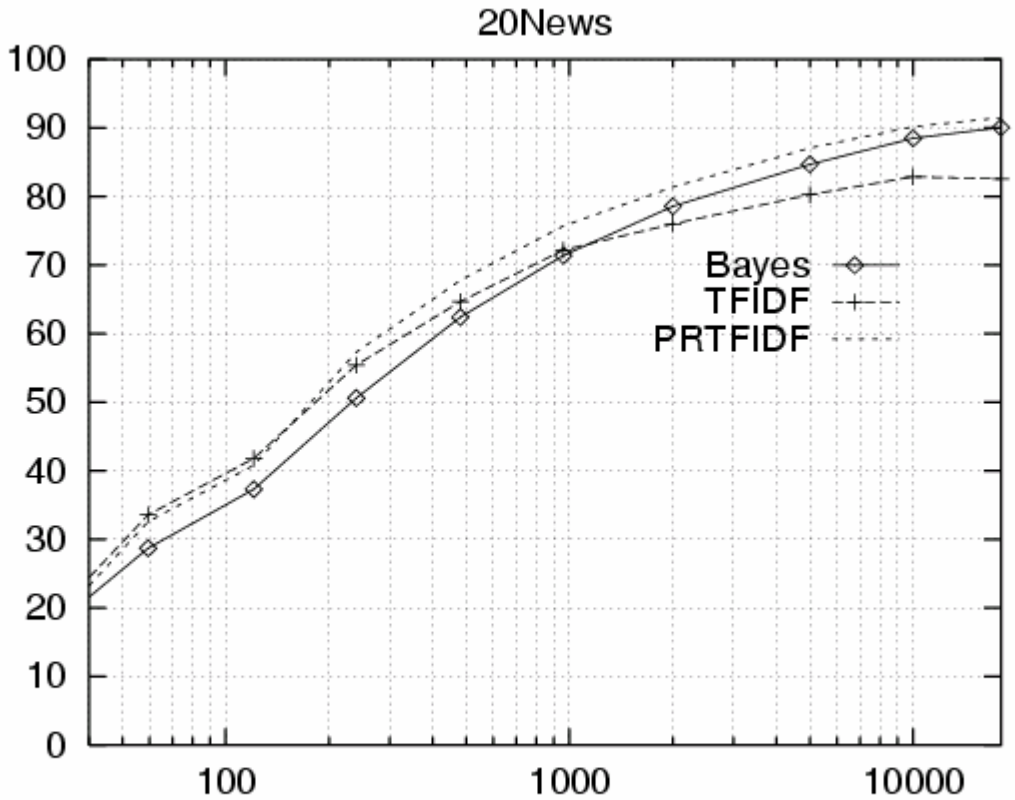
Naive Bayes: 89% classification accuracy

Learning curve for Twenty News Groups



Accuracy vs. Training set size (1/3 withheld for test)

What you need to know

- Training/test/true errors
  - Biased v. unbiased error estimate
  - Never train on the test data!!! (Even if you think you are not doing it)
- Types of learning problems
  - Learning is (just) function approximation!
- Optimal decision using Bayes Classifier
- Naïve Bayes classifier
  - What's the assumption
  - Why we use it
  - How do we learn it
  - Why is Bayesian estimation important
- Text classification
  - Bag of words model
