Semi-supervised learning and discriminative models

- We have seen semi-supervised learning for generative models

- EM

$$\max \log P(X) \stackrel{\substack{X \text{ is visible} \\ Y \text{ hidden}}}{=} \max \log \sum_y P(x, y)$$

- What can we do for discriminative models

- Not regular EM

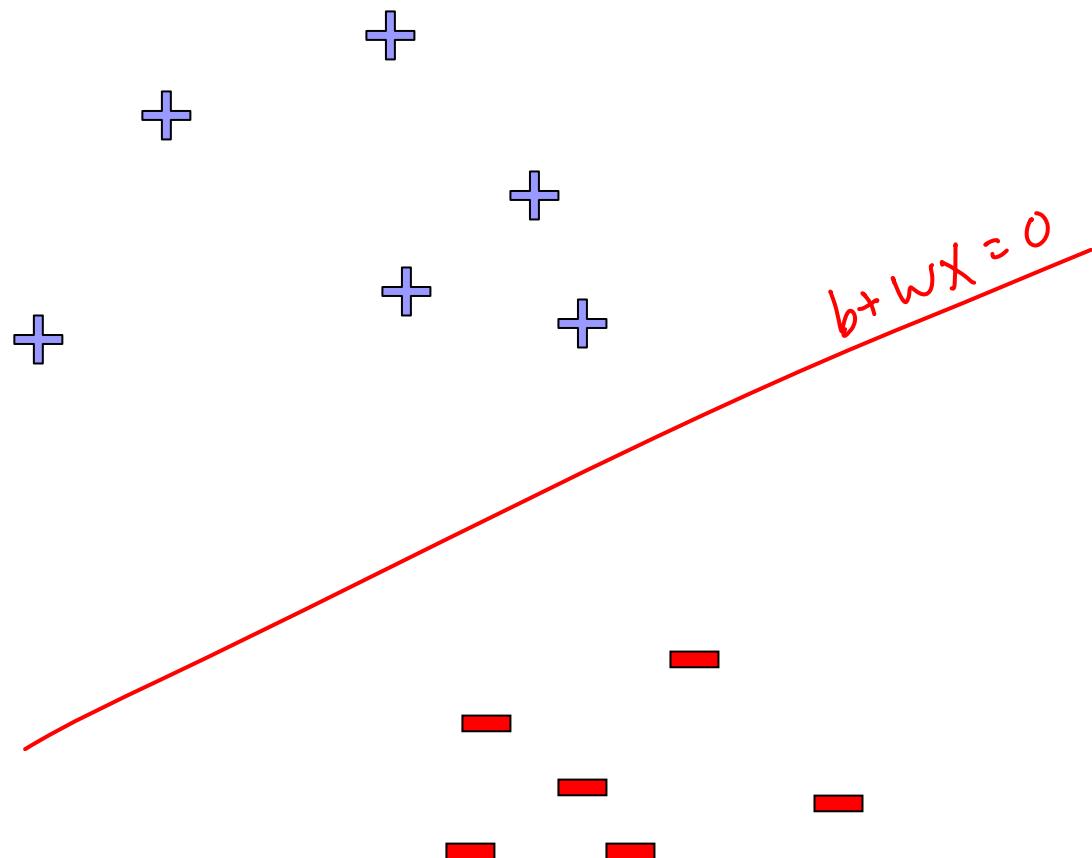

$$P(Y|X) \rightarrow \text{can't compute } p(x)$$

- we can't compute $P(x)$
 - But there are discriminative versions of EM

- Co-Training!

- Many other tricks... let's see an example

Linear classifiers – Which line is better?

Data: *features* *class*

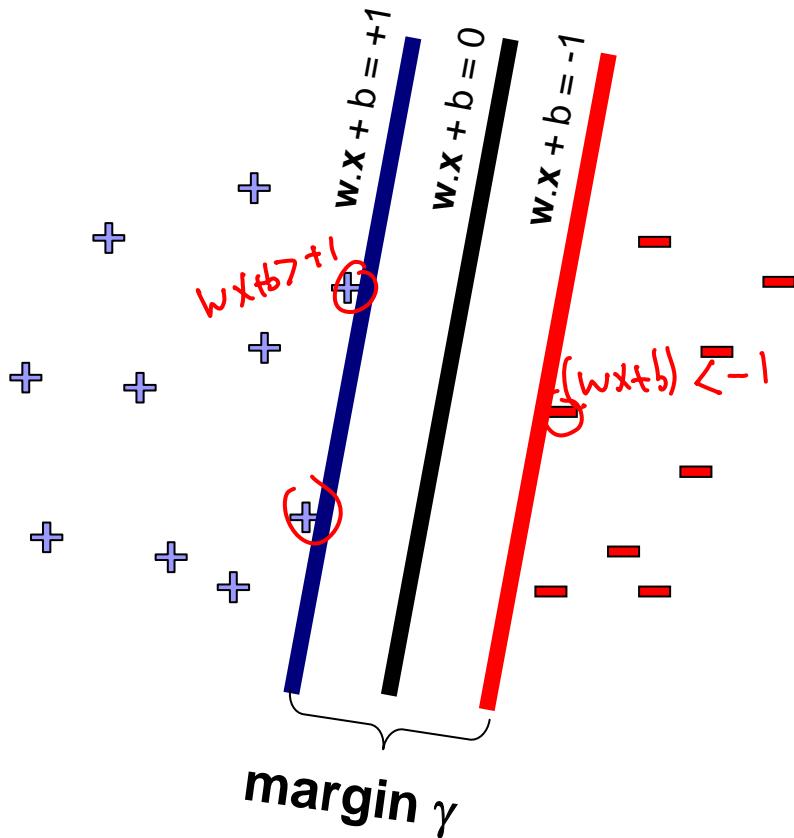

Example i:

$\langle x_i^{(1)}, \dots, x_i^{(m)} \rangle$ — m features

$y_i \in \{-1, +1\}$ — class

$$\mathbf{w} \cdot \mathbf{x} = \sum_j w^{(j)} x^{(j)}$$

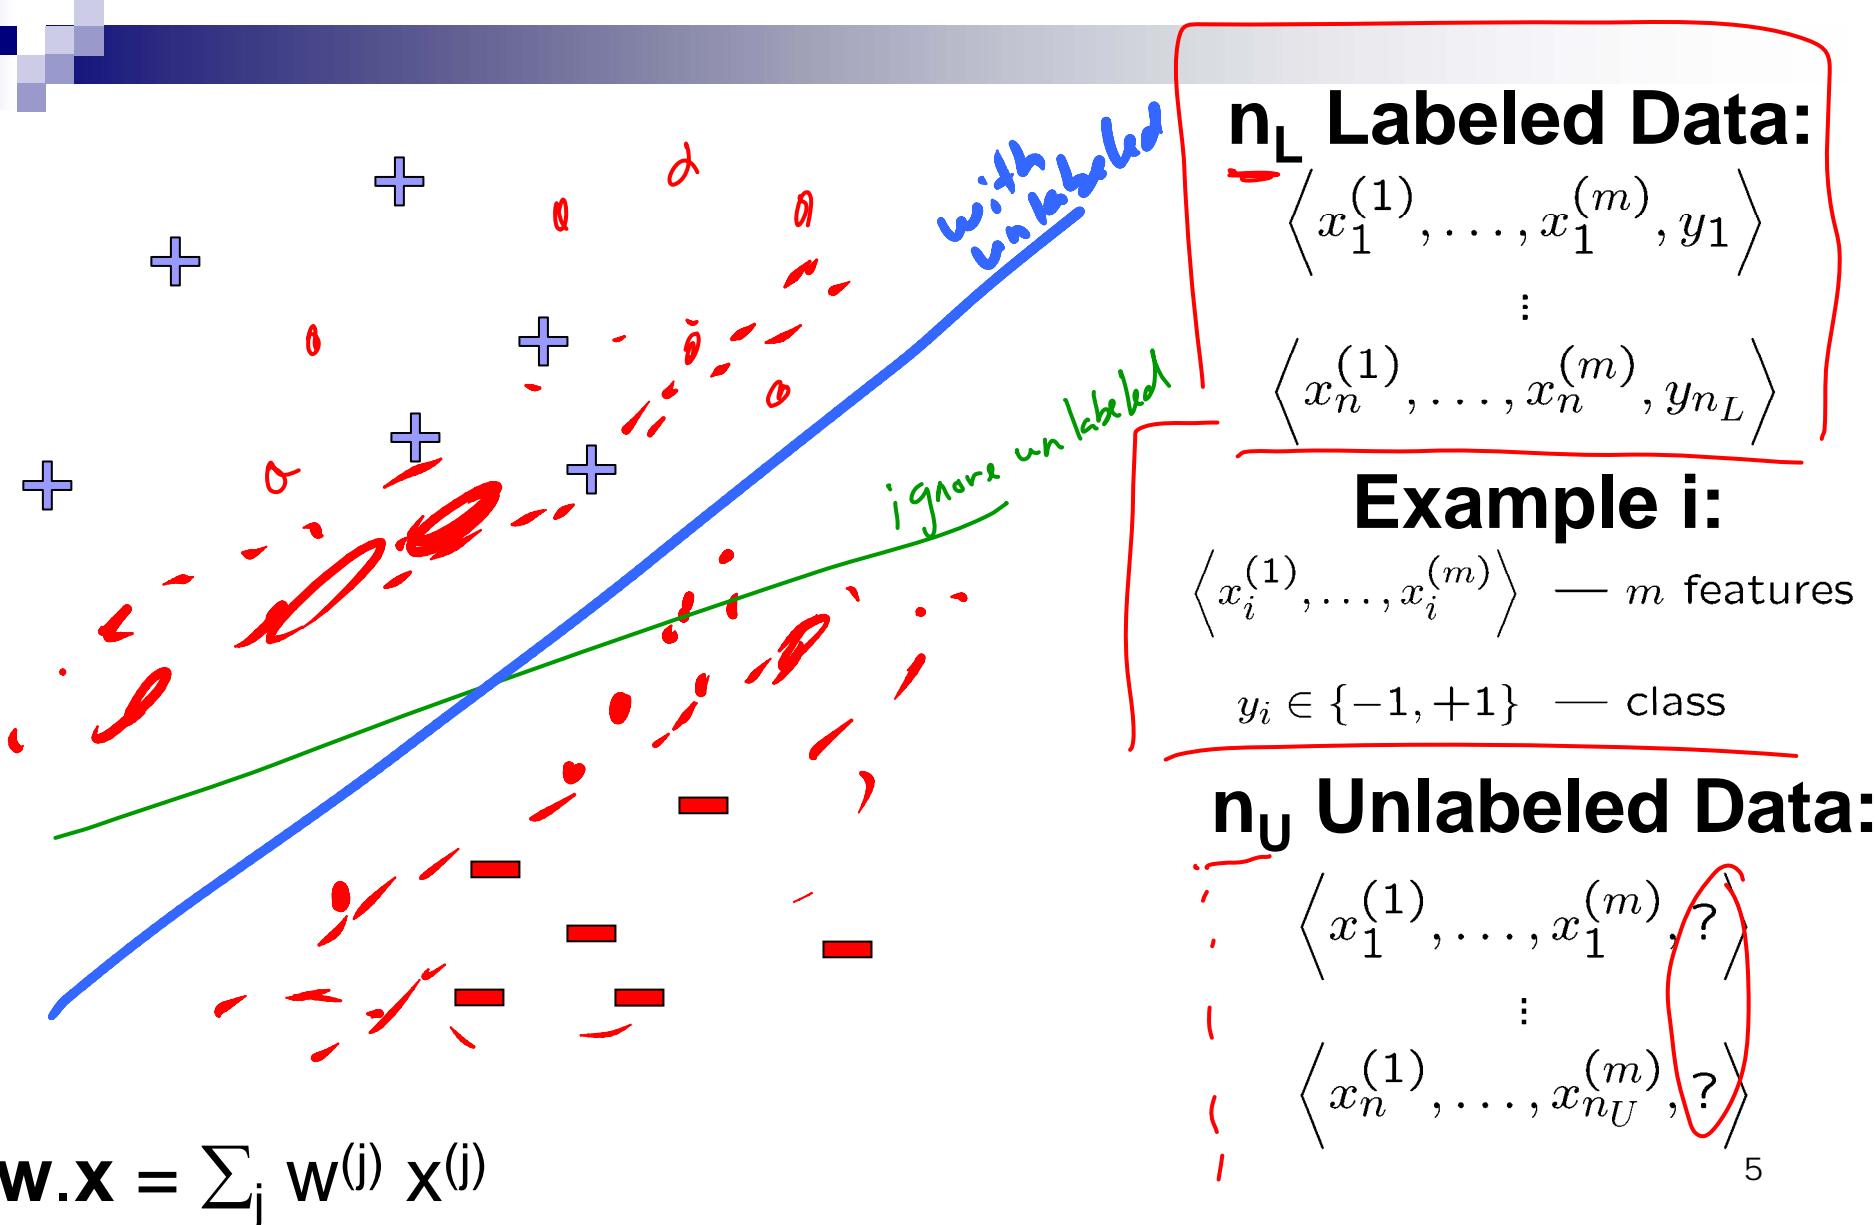

Support vector machines (SVMs)

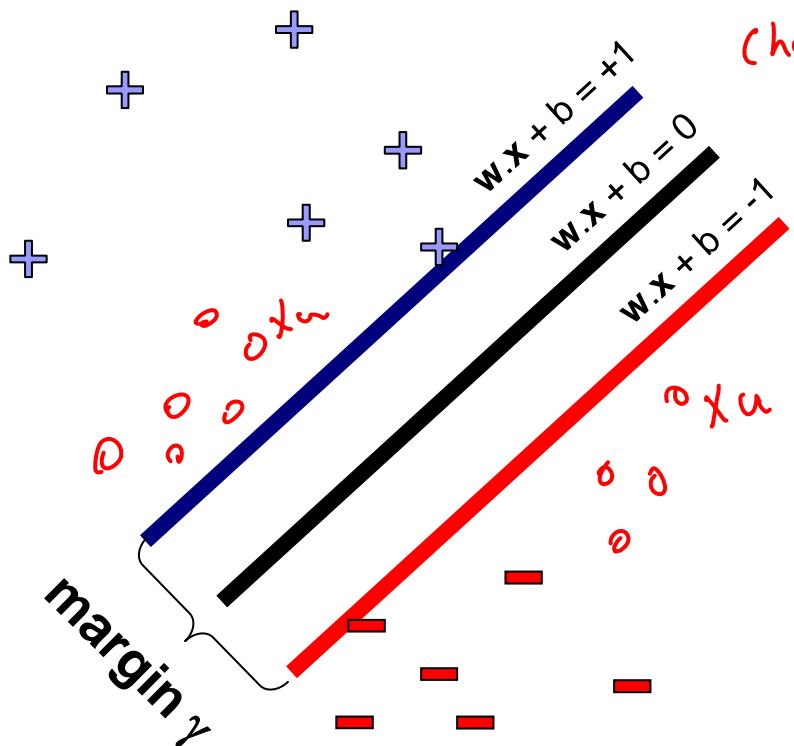

$$\begin{aligned} \text{minimize}_w \quad & w \cdot w \\ \text{subject to} \quad & (w \cdot x_j + b) y_j \geq 1, \quad \forall j \end{aligned}$$

- Solve efficiently by quadratic programming (QP)
 - Well-studied solution algorithms
- Hyperplane defined by support vectors

What if we have unlabeled data?

Transductive support vector machines (TSVMs)

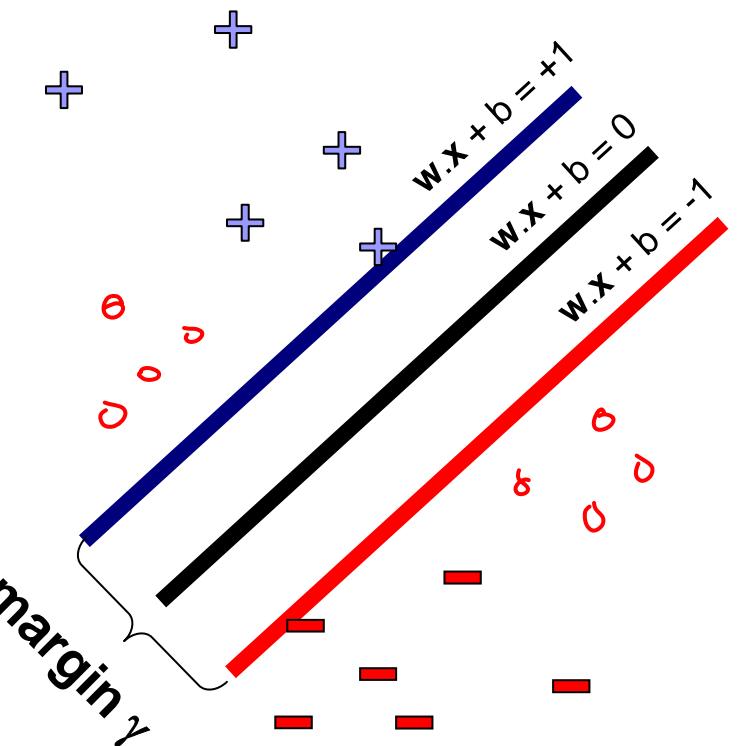

minimize $\underline{w} \cdot \underline{w}$

$\text{choose } \{\hat{y}_1, \dots, \hat{y}_n\}$

$$(w \cdot x_j + b) y_j \geq 1, \forall j \in \mathcal{L}$$
$$(w \cdot x_u + b) \hat{y}_u \geq 1 \quad \forall u \in \mathcal{U}$$
$$\hat{y}_u \in \{+1, -1\} \quad \forall u \in \mathcal{U}$$

Transductive support vector machines (TSVMs)

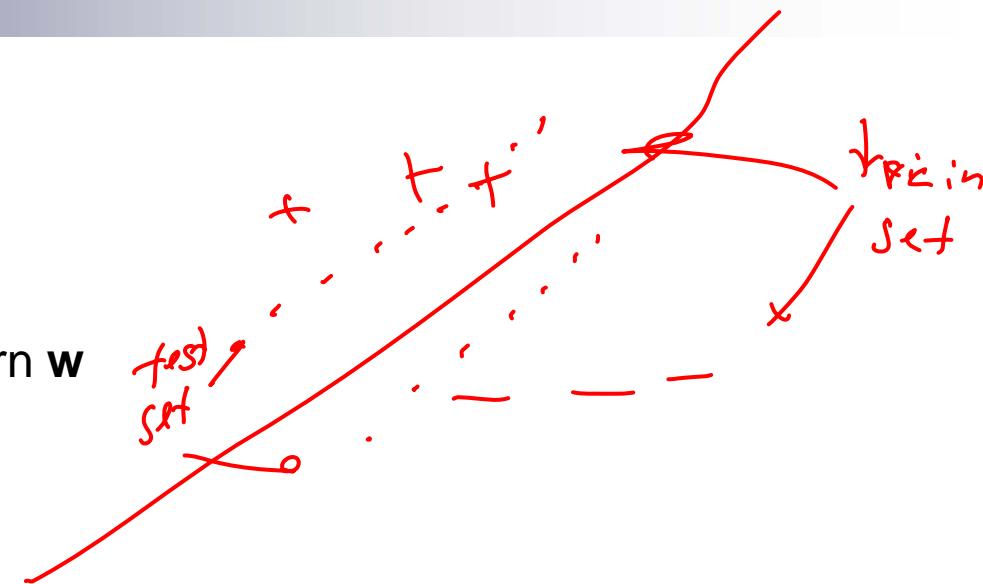

$$\begin{aligned} & \underset{\mathbf{w}, \{\hat{y}_1, \dots, \hat{y}_{n_U}\}}{\text{minimize}} \quad \mathbf{w} \cdot \mathbf{w} \\ & (\mathbf{w} \cdot \mathbf{x}_j + b) y_j \geq 1, \quad \forall j = 1, \dots, n_L \\ & (\mathbf{w} \cdot \mathbf{x}_u + b) \hat{y}_u \geq 1, \quad \forall u = 1, \dots, n_U \\ & \hat{y}_u \in \{-1, +1\}, \quad \forall u = 1, \dots, n_U \end{aligned}$$

bilinear constraint
integer
constraint \Rightarrow hard!

What's the difference between transductive learning and semi-supervised learning?

- Not much, and
- A lot!!!
- **Semi-supervised learning:**
 - labeled and unlabeled data \rightarrow learn w
 - use w on test data
- **Transductive learning**
 - same algorithms for labeled and unlabeled data, but...
 - unlabeled data is test data!!!
- **You are learning on the test data!!!**
 - OK, because you never look at the labels of the test data
 - can get better classification
 - but be very very very very very very very careful!!!
 - never use test data prediction accuracy to tune parameters, select kernels, etc.

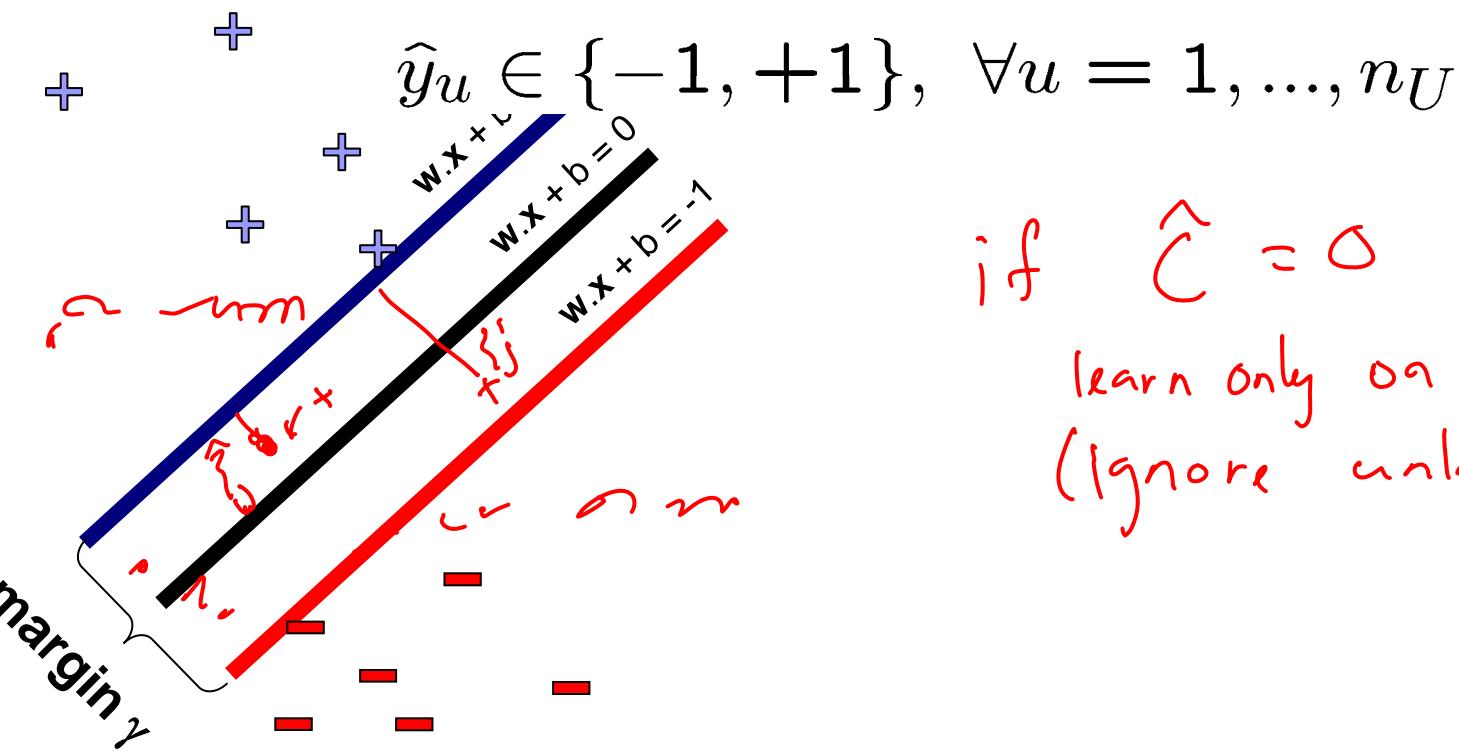

don't look at prediction accuracy!

Adding slack variables

$$\text{minimize}_{\mathbf{w}, \{\hat{y}_1, \dots, \hat{y}_{n_U}\}} \quad \mathbf{w} \cdot \mathbf{w} + C \sum_{j=1}^L \xi_j + \hat{C} \sum_{u=1}^{n_U} \xi_u$$

$$(\mathbf{w} \cdot \mathbf{x}_j + b) y_j \geq 1 - \xi_j \quad \forall j = 1, \dots, n_L$$

$$(\mathbf{w} \cdot \mathbf{x}_u + b) \hat{y}_u \geq 1 - \xi_u \quad \forall u = 1, \dots, n_U$$

if $\hat{C} = 0$

learn only on labeled data
(ignore unlabeled data)

Transductive SVMs – now with slack variables! [Vapnik 98]

Optimize $\mathbf{w}, \{\xi_1, \dots, \xi_{n_L}\}, \{\hat{y}_1, \dots, \hat{y}_{n_U}\}, \{\hat{\xi}_1, \dots, \hat{\xi}_{n_U}\}$

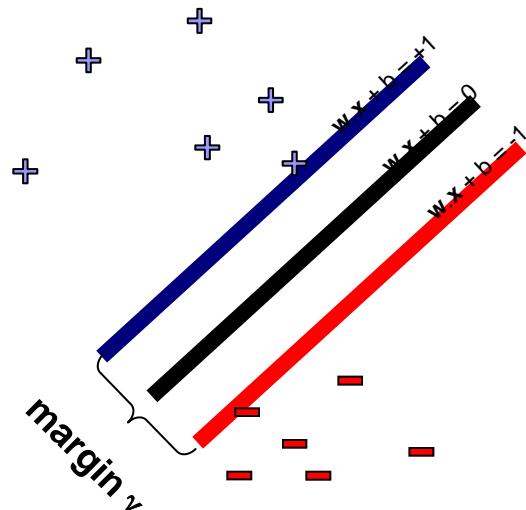

weight labeled slacks class of unlabeled unlabeled slacks

minimize $\mathbf{w} \cdot \mathbf{w} + C \sum_j \xi_j + \hat{C} \sum_u \hat{\xi}_u$

$(\mathbf{w} \cdot \mathbf{x}_j + b) y_j \geq 1 - \xi_j, \quad \forall j = 1, \dots, n_L$

$(\mathbf{w} \cdot \mathbf{x}_u + b) \hat{y}_u \geq 1 - \hat{\xi}_u, \quad \forall u = 1, \dots, n_U$

$\hat{y}_u \in \{-1, +1\}, \quad \forall u = 1, \dots, n_U$

Learning Transductive SVMs is hard!

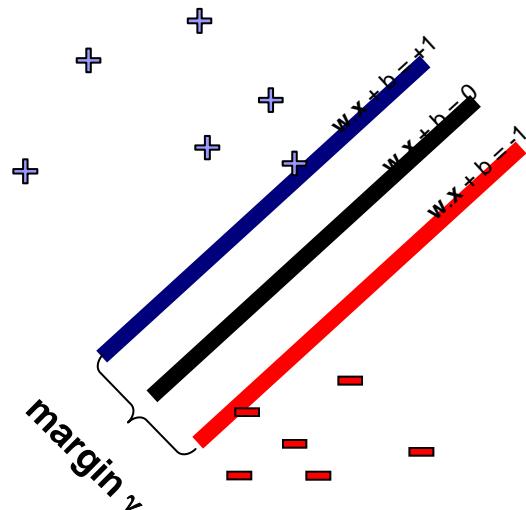

Optimize $\mathbf{w}, \{\xi_1, \dots, \xi_{n_L}\}, \{\hat{y}_1, \dots, \hat{y}_{n_U}\}, \{\hat{\xi}_1, \dots, \hat{\xi}_{n_U}\}$

$$\text{minimize } \mathbf{w} \cdot \mathbf{w} + C \sum_j \xi_j + \hat{C} \sum_u \hat{\xi}_u$$

$$(\mathbf{w} \cdot \mathbf{x}_j + b) y_j \geq 1 - \xi_j, \quad \forall j = 1, \dots, n_L$$

$$(\mathbf{w} \cdot \mathbf{x}_u + b) \hat{y}_u \geq 1 - \hat{\xi}_u, \quad \forall u = 1, \dots, n_u$$

$$\hat{y}_u \in \{-1, +1\}, \quad \forall u = 1, \dots, n_u$$

■ Integer Program

□ NP-hard!!!

□ Well-studied solution algorithms,
but will not scale up to very large
problems *100 000 datapoints*

A (heuristic) learning algorithm for Transductive SVMs [Joachims 99]

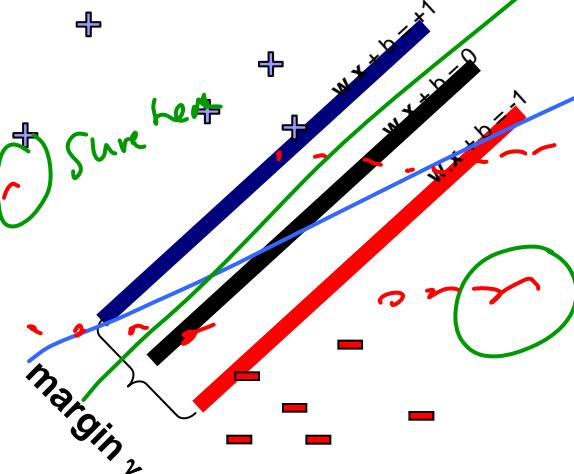

$$\text{minimize} \quad \mathbf{w} \cdot \mathbf{w} + C \sum_j \xi_j + \hat{C} \sum_u \hat{\xi}_u$$

$$(\mathbf{w} \cdot \mathbf{x}_j + b) y_j \geq 1 - \xi_j, \quad \forall j = 1, \dots, n_L$$

$$(\mathbf{w} \cdot \mathbf{x}_u + b) \hat{y}_u \geq 1 - \hat{\xi}_u, \quad \forall u = 1, \dots, n_u$$

$$\hat{y}_u \in \{-1, +1\}, \quad \forall u = 1, \dots, n_u$$

- *very sure* → set it to +
- *first iteration*
- If you set \hat{C} to zero → ignore unlabeled data
- Intuition of algorithm:

- start with small \hat{C}
- add labels to some unlabeled data based on classifier prediction *if classifier very sure about $x_u \rightarrow$ label it*
- slowly increase \hat{C}
- keep on labeling unlabeled data and re-running classifier

Some results classifying news articles – from [Joachims 99]

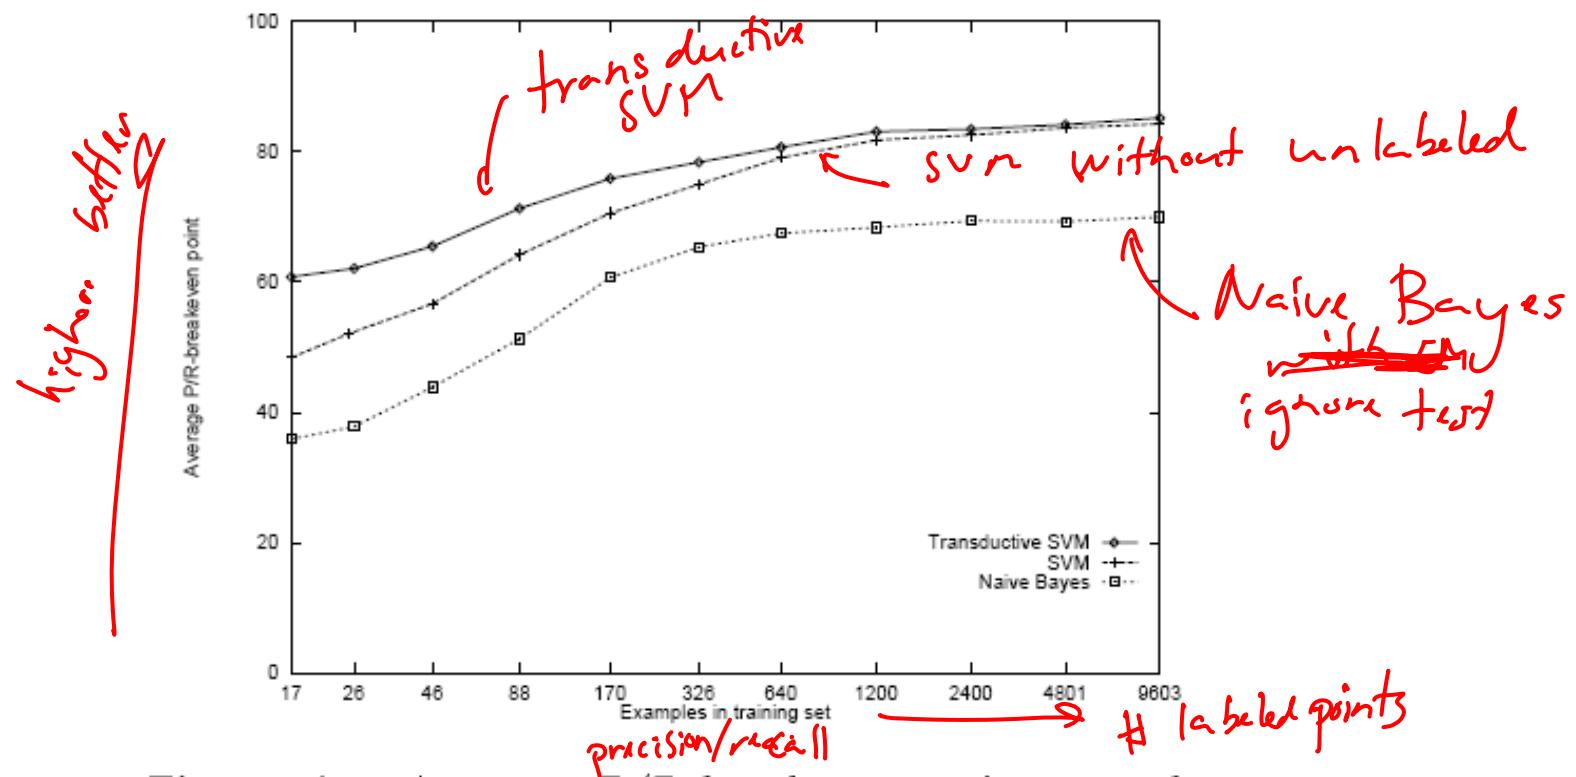

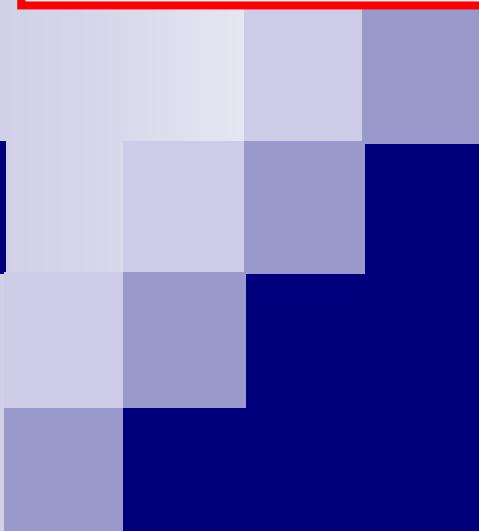

Figure 6: Average P/R-breakeven point on the Reuters dataset for different training set sizes and a test set size of 3,299. unlabeled

What you need to know about transductive SVMs

- What is transductive v. semi-supervised learning
- Formulation for transductive SVM
 - can also be used for semi-supervised learning
- Optimization is hard!
 - Integer program
- There are simple heuristic solution methods that work well here

Wall et al. 2003 (PCA applied to gene expression data)

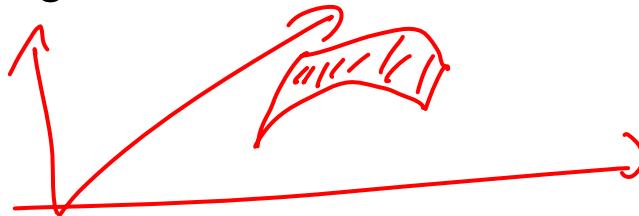

Dimensionality reduction

Machine Learning – 10701/15781
Carlos Guestrin
Carnegie Mellon University

April 24th, 2006

Dimensionality reduction

- Input data may have thousands or millions of dimensions!
 - e.g., text data has
 - *about 10,000 – 100,000 single words*
 - *pairs of words* → *100,000² features*
- **Dimensionality reduction:** represent data with fewer dimensions
 - easier learning – fewer parameters
 - visualization – hard to visualize more than 3D or 4D
 - discover “intrinsic dimensionality” of data
 - high dimensional data that is truly lower dimensional

Feature selection

- Want to learn $f: \mathbf{X} \mapsto \mathbf{Y}$ *for classification*
 - $\mathbf{X} = \langle X_1, \dots, X_n \rangle$
 - but some features are more important than others
- **Approach:** select subset of features to be used by learning algorithm
 - Score each feature (or sets of features)
 - Select set of features with best score

Simple greedy forward feature selection algorithm

- Pick a dictionary of features
 - e.g., polynomials for linear regression
- Greedy heuristic:
 - Start from empty (or simple) set of features $F_0 = \emptyset$
 - Run learning algorithm for current set of features F_t
 - Obtain h_t *hypothesis*
 - Select **next best feature X_i**
 - e.g., X_j that results in lowest cross-validation error learner when learning with $F_t \cup \{X_j\}$
 - $F_{t+1} \leftarrow F_t \cup \{X_i\}$ *add in best feature*
 - Recurse

$\{1, x, x^2, \dots\}$

$\{1, x\}$

{ here other criteria
- mutual info.
- χ^2 -squared test
- ...
- ...}

Simple greedy backward feature selection algorithm

- Pick a dictionary of features
 - e.g., polynomials for linear regression
- Greedy heuristic:
 - Start from all features $F_0 = F$
 - Run learning algorithm for current set of features F_t
 - Obtain $\underline{h_t}$
 - Select next worst feature X_i
 - e.g., X_j that results in lowest cross-validation error learner when learning with $F_t - \{X_j\}$ *remove*
 - $F_{t+1} \leftarrow F_t - \{X_i\}$ *remove it.*
 - Recurse

Impact of feature selection on classification of fMRI data [Pereira et al. '05]

Accuracy classifying category of word read by subject

all (~2500)	0.638	0.767	0.767	0.25	0.75	0.833	0.567	0.433	0.733

Table 1: Average accuracy across all pairs of categories, restricting the procedure to use a certain number of voxels for each subject. The highlighted line corresponds to the best mean accuracy, obtained using 300 voxels.

Voxels scored by p-value of regression to predict voxel value from the task

Lower dimensional projections

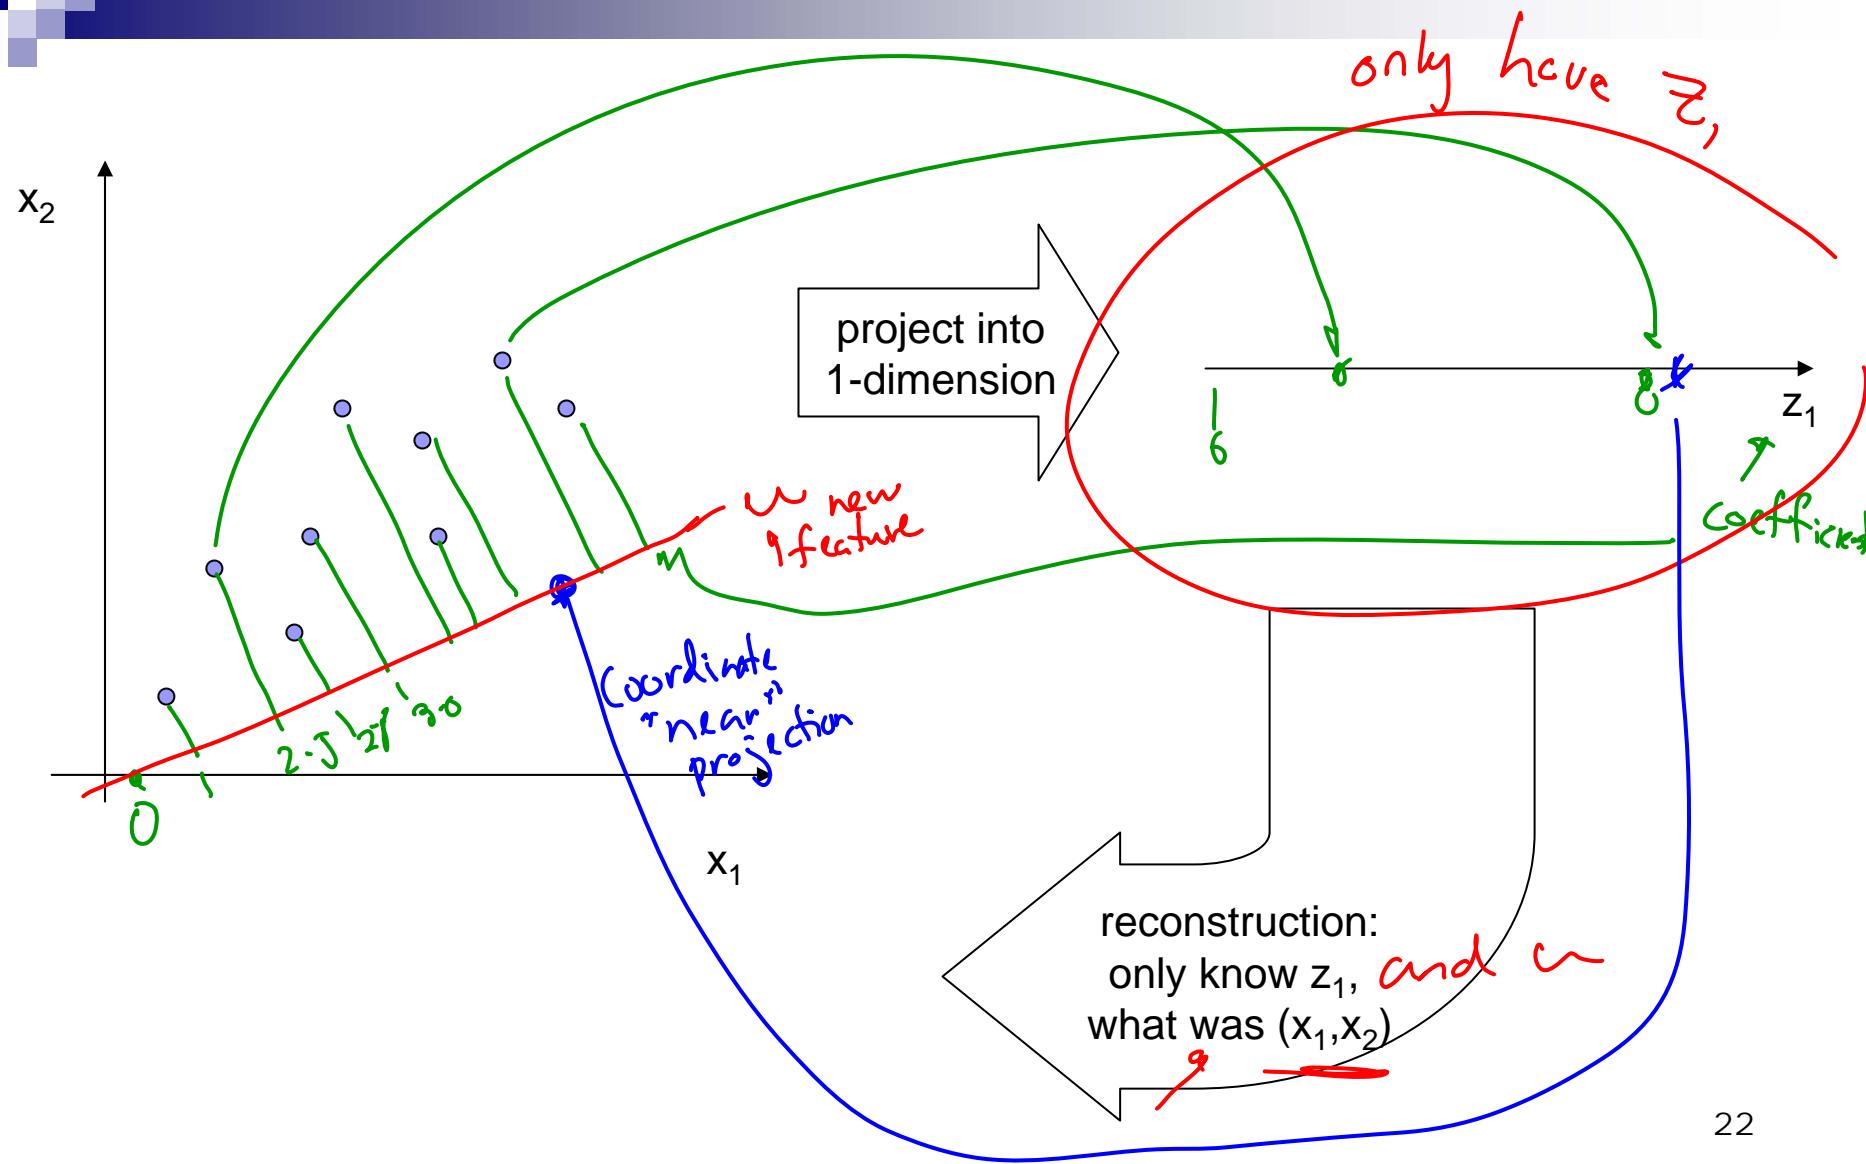

- Rather than picking a subset of the features, we can generate new features that are combinations of existing features

$$x_{\text{new}} = 10x^2 + 17x - 28x^{-2}$$
$$x_{\text{new}} = g(x)$$

- Let's see this in the unsupervised setting

- just X , but no Y
ignore / don't have

Liner projection and reconstruction

Principal component analysis – basic idea

- Project n -dimensional data into k -dimensional space while preserving information:
 - e.g., project space of 10000 words into 3-dimensions
 - e.g., project 3-d into 2-d
- Choose projection with minimum reconstruction error

Linear projections, a review

- Project a point into a (lower dimensional) space:

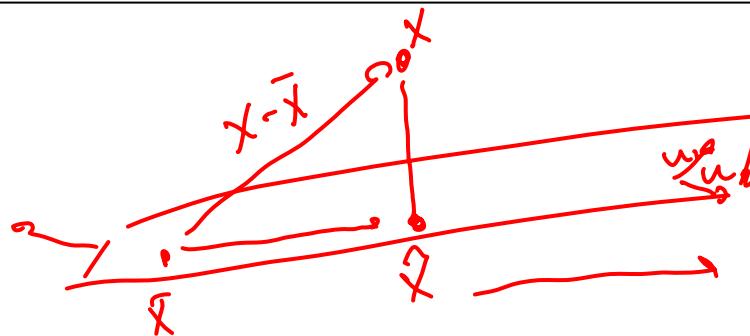

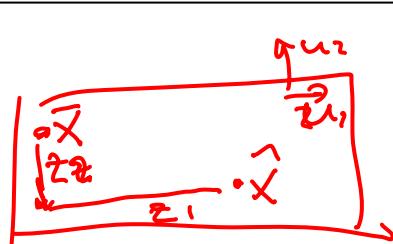

- **point**: $\mathbf{x} = (x_1, \dots, x_n)$
 - **select a basis** – set of basis vectors – $(\mathbf{u}_1, \dots, \mathbf{u}_k)$

- we consider orthonormal basis: $\mathbf{u}_i = \begin{smallmatrix} \uparrow \\ \mathbf{u}_i \end{smallmatrix}$, $\mathbf{u}_i \cdot \mathbf{u}_j = 0$ for $i \neq j$

- **select a center** – $\bar{\mathbf{x}}$, defines offset of space
 - **best coordinates** in lower dimensional space defined by dot-products: (z_1, \dots, z_k) , $z_i = (\mathbf{x} - \bar{\mathbf{x}}) \cdot \mathbf{u}_i$

$$\mathbf{a} \cdot \mathbf{b} = \sum_{i=1}^n a_i b_i$$

- minimum squared error

$$\mathbf{x} = \bar{\mathbf{x}} + \sum_{i=1}^k z_i \mathbf{u}_i$$

PCA finds projection that minimizes reconstruction error

- Given m data points: $\mathbf{x}^i = (x_1^i, \dots, x_n^i)$, $i=1 \dots m$
- Will represent each point as a projection:

□ $\hat{\mathbf{x}}^i = \bar{\mathbf{x}} + \sum_{j=1}^k z_j^i \mathbf{u}_j$ where: $\bar{\mathbf{x}} = \frac{1}{m} \sum_{i=1}^m \mathbf{x}^i$ and $z_j^i = \mathbf{x}^i \cdot \mathbf{u}_j$

Project average projection average of m points

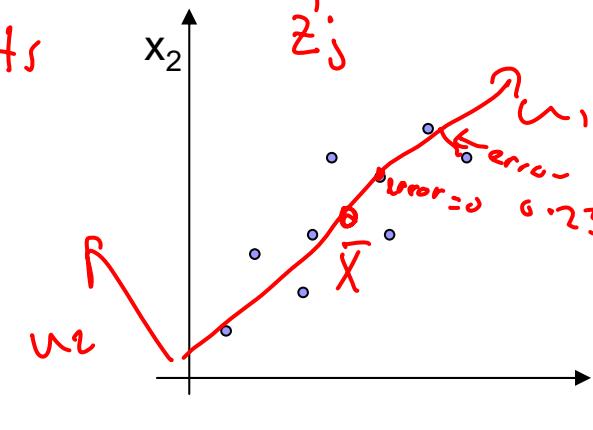

dot product is coordinate z_j^i

■ PCA:

- Given $k \leq n$, find $(\mathbf{u}_1, \dots, \mathbf{u}_k)$ minimizing reconstruction error:

$$\text{error}_k = \sum_{i=1}^m (\mathbf{x}^i - \hat{\mathbf{x}}^i)^2$$

true location projected location

Understanding the reconstruction error

Only use
first K
u

- Note that $\underline{x^i}$ can be represented exactly by n -dimensional projection:

$$\underline{x^i} = \bar{x} + \sum_{j=1}^n z_j^i \mathbf{u}_j$$

define $\mathbf{u} = (\mathbf{u}_1, \dots, \mathbf{u}_n)$

$$\hat{\mathbf{x}}^i = \bar{\mathbf{x}} + \sum_{j=1}^k z_j^i \mathbf{u}_j \quad z_j^i = \mathbf{x}^i \cdot \mathbf{u}_j$$

Given $k \leq n$, find $(\mathbf{u}_1, \dots, \mathbf{u}_k)$ minimizing reconstruction error:

$$\text{error}_k = \sum_{i=1}^m (\mathbf{x}^i - \hat{\mathbf{x}}^i)^2$$

$$(a+b)^2 = \underbrace{a^2 + b^2}_{a^2} + \underbrace{2ab + b^2}_{2ab}$$

exactly

$$\text{error}_K = \sum_{i=1}^m (\mathbf{x}_i - \hat{\mathbf{x}}_i)^2$$

- Rewriting error:

$$\begin{aligned}
 &= \sum_{i=1}^m \left[\bar{\mathbf{x}} + \sum_{j=1}^n z_j^i \mathbf{u}_j - \left(\bar{\mathbf{x}} + \sum_{j=1}^K z_j^i \mathbf{u}_j \right) \right]^2 = \sum_{i=1}^m \left[\sum_{j=K+1}^n z_j^i \mathbf{u}_j \right]^2 \\
 &= \sum_{i=1}^m \sum_{j=K+1}^n (z_j^i \mu_j)^2 + \sum_{i=1}^m \sum_{j=K+1}^n \sum_{v=K+1}^n \underbrace{[z_j^i \mathbf{u}_j \cdot z_v^i \mathbf{u}_v]}_{\mu_j \cdot \mu_v = 0 \text{ (orthogonal)}} \\
 &= \sum_{i=1}^m \sum_{j=K+1}^n (\mu_j \cdot (\mathbf{x}_i - \bar{\mathbf{x}}) \mu_j)^2
 \end{aligned}$$

$\mathbf{z}_j^i = \mathbf{u}_j \cdot (\mathbf{x}_i - \bar{\mathbf{x}})$

Reconstruction error and covariance matrix

$$\begin{aligned} a^2 &= a^T a \\ &= (a \cdot b)^2 \\ &= a^T b \quad b^T a \end{aligned}$$

$$u_i \text{ is } \sim b^T a$$

$$error_k = \sum_{i=1}^m \sum_{j=k+1}^n [u_j \cdot (x^i - \bar{x})]^2$$

$$= \sum_{i=1}^m \sum_{j=k+1}^n [u_j^T (x^i - \bar{x}) (x^i - \bar{x})^T u_j]$$

$$= \sum_{j=k+1}^n \sum_{i=1}^m u_j^T (x^i - \bar{x}) (x^i - \bar{x})^T u_j$$

$$= \sum_{j=k+1}^n u_j^T \left[\sum_{i=1}^m (x^i - \bar{x}) (x^i - \bar{x})^T \right] u_j$$

$m \cdot \Sigma \leftarrow$ covariance matrix
of data

$$(x^i - \bar{x}) (x^i - \bar{x})^T = \begin{bmatrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{bmatrix} \begin{bmatrix} (x^i_1 - \bar{x}_1) & \dots & (x^i_l - \bar{x}_l) \\ (x^i_2 - \bar{x}_2) & \dots & \vdots \\ \vdots & \dots & \vdots \\ (x^i_n - \bar{x}_n) & \dots & (x^i_l - \bar{x}_l) \end{bmatrix} \sigma_{j,l}$$

$$\Sigma = \frac{1}{m} \sum_{i=1}^m (x^i - \bar{x})(x^i - \bar{x})^T$$

$$error_k = \sum_{i=1}^m \sum_{j=k+1}^n [u_j \cdot (x^i - \bar{x})] u_j$$

scalar \downarrow n vector \downarrow

$$(z_j \cdot u_j)^2$$

$$= z_j^T u_j u_j^T u_j z_j$$

$$= z_j^T z_j$$

$$z_j^i = u_j \cdot (x^i - \bar{x})$$

$u_j^T u_j = 1$
orthonormal

Minimizing reconstruction error and eigen vectors

- Minimizing reconstruction error equivalent to picking orthonormal basis $(\mathbf{u}_1, \dots, \mathbf{u}_n)$ minimizing:

$$\text{error}_k = \sum_{j=k+1}^n \mathbf{u}_j^T \Sigma \mathbf{u}_j \quad \leftarrow \text{consider ignored vectors in error}$$

- Eigen vector:

$$\mathbf{u}: \sum \mathbf{u} = \lambda \mathbf{u} \Rightarrow \mathbf{u}^T \Sigma \mathbf{u} = \lambda \mathbf{u}^T \mathbf{u} = \lambda$$

eigen vector *eigen value*

- Minimizing reconstruction error equivalent to picking $(\mathbf{u}_{k+1}, \dots, \mathbf{u}_n)$ to be eigen vectors with smallest eigen values

take eigen vectors values of Σ

sort!

$\lambda_1 > \lambda_2 > \dots > \lambda_n$

\mathbf{u}_1	λ_1
\mathbf{u}_2	λ_2
\vdots	\vdots

minimize error_k

$$\Rightarrow \min_{\mathbf{u}} \sum_{j=k+1}^n \mathbf{u}_j^T \Sigma \mathbf{u}_j$$

$$= \min_{\mathbf{u}} \sum_{j=k+1}^n \lambda_j$$

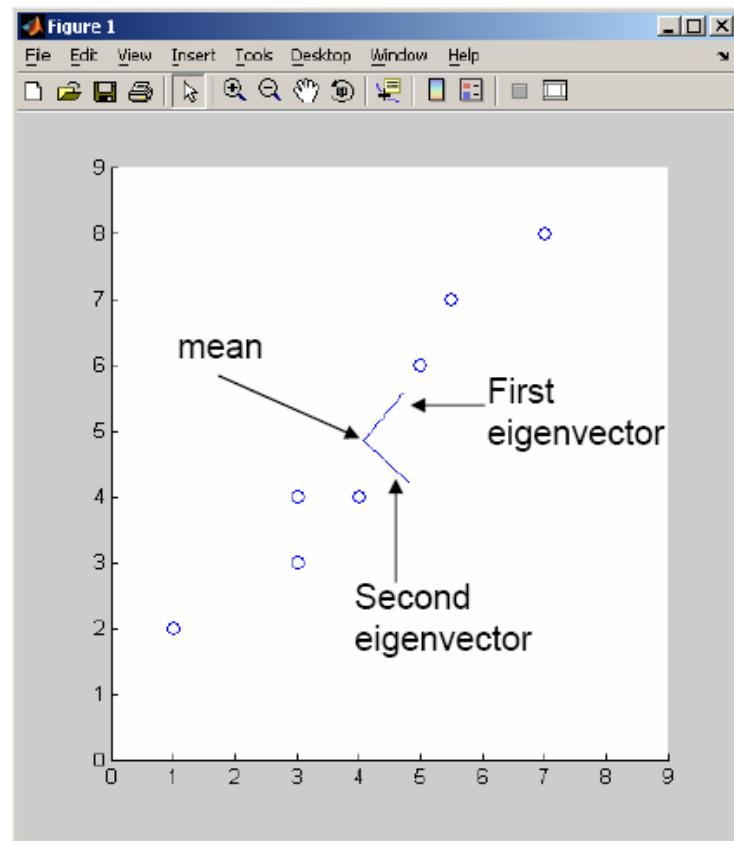

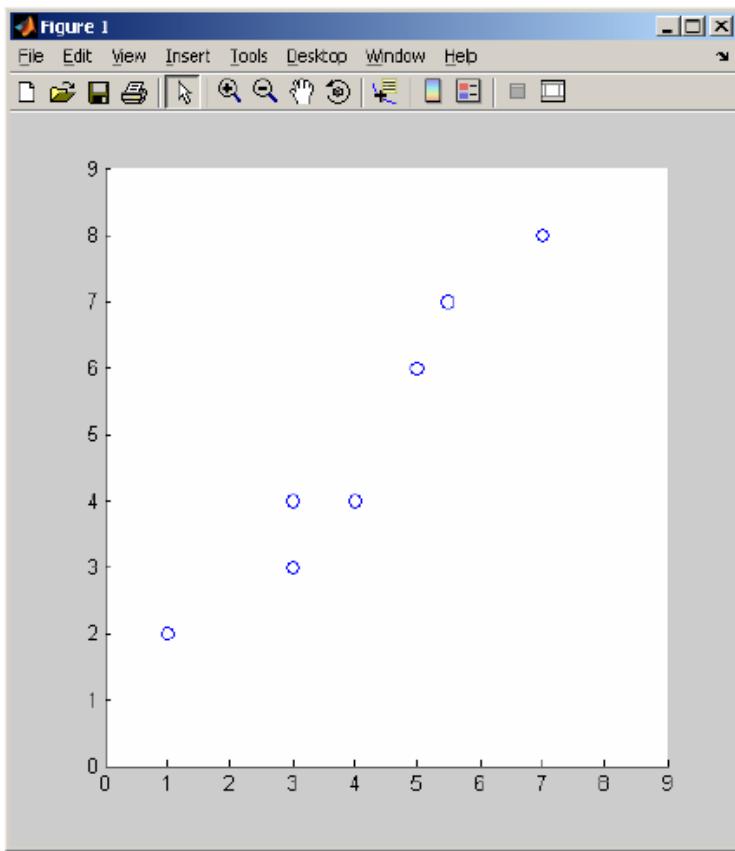

\Rightarrow ignore vectors with low eigen values

Basic PCA algorithm

- Start from m by n data matrix \mathbf{X}
- **Recenter**: subtract mean from each row of \mathbf{X}
 - $\mathbf{X}_c \leftarrow \mathbf{X} - \bar{\mathbf{X}}$
- **Compute covariance matrix**:
 - $\Sigma \leftarrow \mathbf{X}_c^T \mathbf{X}_c$
- Find **eigen vectors and values** of Σ
- **Principal components**: k eigen vectors with highest eigen values

PCA example

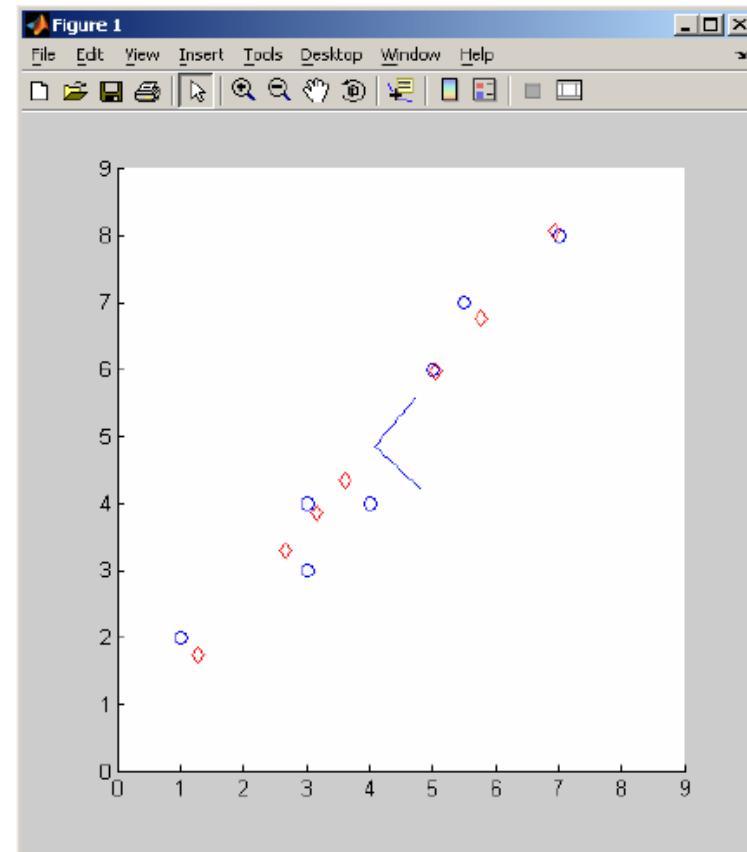

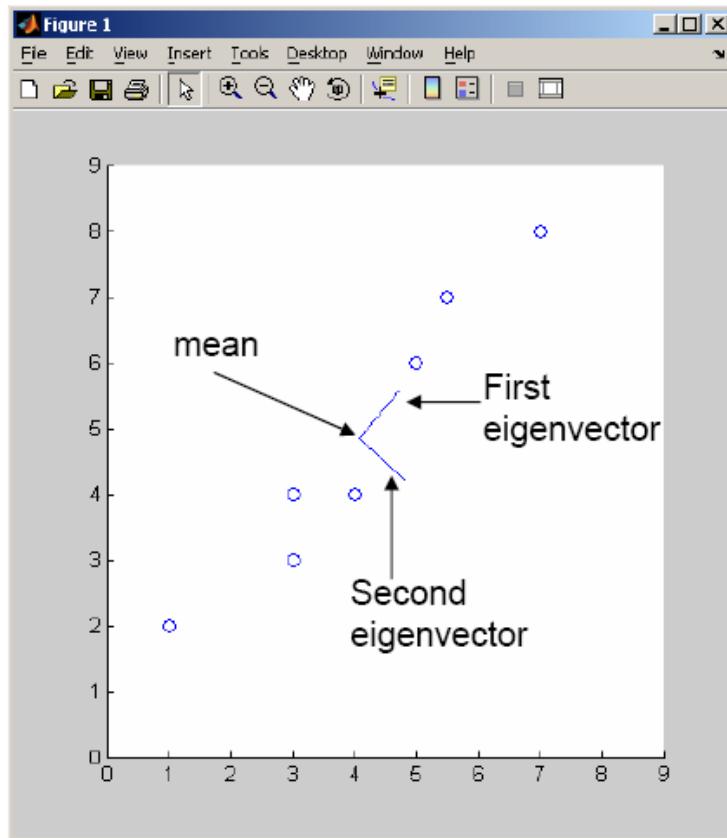

$$\hat{\mathbf{x}}^i = \bar{\mathbf{x}} + \sum_{j=1}^k z_j^i \mathbf{u}_j$$

PCA example – reconstruction

$$\hat{\mathbf{x}}^i = \bar{\mathbf{x}} + \sum_{j=1}^k z_j^i \mathbf{u}_j$$

only used first principal component

Eigenfaces [Turk, Pentland '91]

- Input images:

- Principal components:

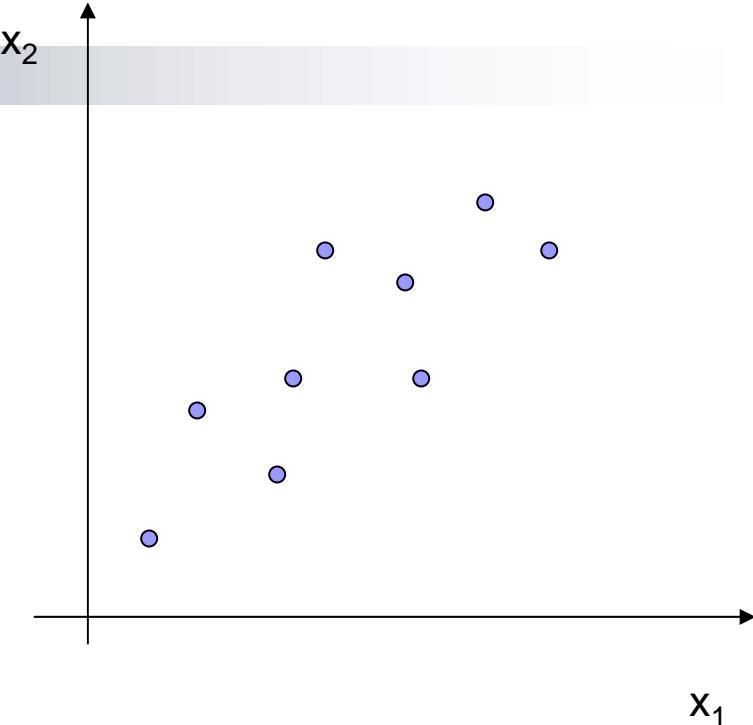

Eigenfaces reconstruction

- Each image corresponds to adding 8 principal components:

Relationship to Gaussians

- PCA assumes data is Gaussian
 - $\mathbf{x} \sim N(\bar{\mathbf{x}}; \Sigma)$
- Equivalent to weighted sum of simple Gaussians:
$$\mathbf{x} = \bar{\mathbf{x}} + \sum_{j=1}^n z_j \mathbf{u}_j; \quad z_j \sim N(0; \sigma_j^2)$$
- Selecting top k principal components equivalent to lower dimensional Gaussian approximation:
$$\mathbf{x} \approx \bar{\mathbf{x}} + \sum_{j=1}^k z_j \mathbf{u}_j + \varepsilon; \quad z_j \sim N(0; \sigma_j^2)$$
 - $\varepsilon \sim N(0; \sigma^2)$, where σ^2 is defined by error_k

Scaling up

- Covariance matrix can be really big!
 - Σ is n by n
 - 10000 features $\rightarrow |\Sigma|$
 - finding eigenvectors is very slow...
- Use singular value decomposition (SVD)
 - finds k eigenvectors
 - great implementations available, e.g., Matlab svd

SVD

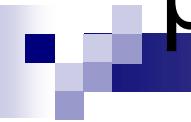

- Write $\mathbf{X} = \mathbf{U} \mathbf{S} \mathbf{V}^T$
 - $\mathbf{X} \leftarrow$ data matrix, one row per datapoint
 - $\mathbf{U} \leftarrow$ weight matrix, one row per datapoint – coordinate of \mathbf{x}^i in eigenspace
 - $\mathbf{S} \leftarrow$ singular value matrix, diagonal matrix
 - in our setting each entry is eigenvalue λ_j
 - $\mathbf{V}^T \leftarrow$ singular vector matrix
 - in our setting each row is eigenvector \mathbf{v}_j

PCA using SVD algorithm

- Start from m by n data matrix \mathbf{X}
- **Recenter**: subtract mean from each row of \mathbf{X}
 - $\mathbf{X}_c \leftarrow \mathbf{X} - \bar{\mathbf{X}}$
- Call SVD algorithm on \mathbf{X}_c – ask for k singular vectors
- **Principal components**: k singular vectors with highest singular values (rows of \mathbf{V}^T)
 - **Coefficients** become:

Using PCA for dimensionality reduction in classification

- Want to learn $f: \mathbf{X} \mapsto \mathbf{Y}$
 - $\mathbf{X} = \langle X_1, \dots, X_n \rangle$
 - but some features are more important than others
- **Approach:** Use PCA on \mathbf{X} to select a few important features

PCA for classification can lead to problems...

- Direction of maximum variation may be unrelated to “discriminative” directions:
- PCA often works very well, but sometimes must use more advanced methods
 - e.g., Fisher linear discriminant

What you need to know

- Dimensionality reduction
 - why and when it's important
- Simple feature selection
- Principal component analysis
 - minimizing reconstruction error
 - relationship to covariance matrix and eigenvectors
 - using SVD
 - problems with PCA
