15-853: Algorithms in the Real World

Data Compression 4

Compression Outline

Introduction: Lossy vs. Lossless, Benchmarks, ...

Information Theory: Entropy, etc.

Probability Coding: Huffman + Arithmetic Coding

Applications of Probability Coding: PPM + others

Lempel-Ziv Algorithms: LZ77, gzip, compress, ...

Other Lossless Algorithms: Burrows-Wheeler

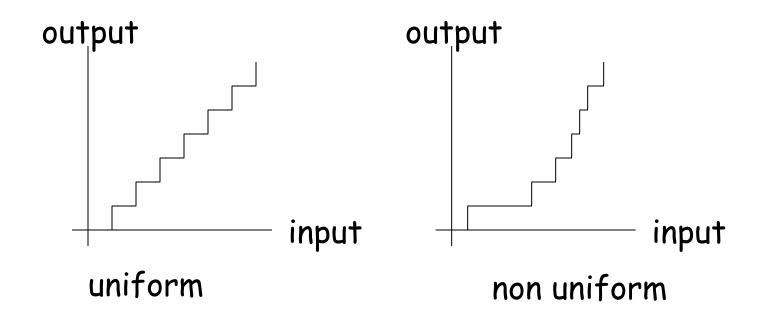

Lossy algorithms for images: JPEG, MPEG, ...

- Scalar and vector quantization
- JPEG and MPEG

Compressing graphs and meshes: BBK

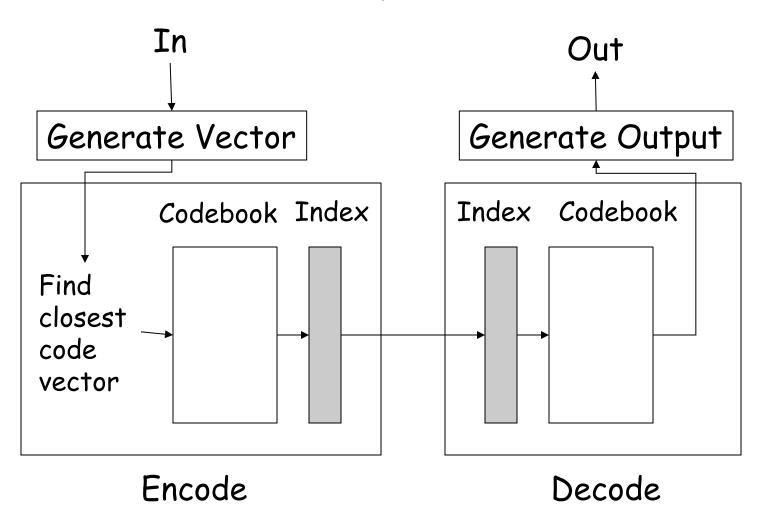

Scalar Quantization

Quantize regions of values into a single value:

Can be used to reduce # of bits for a pixel

Vector Quantization

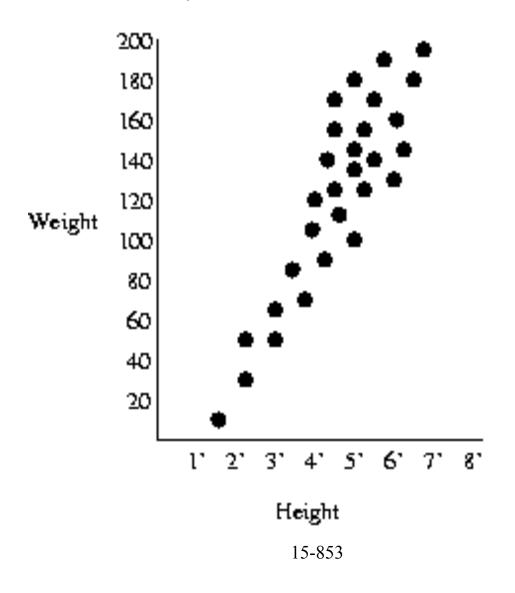

Vector Quantization

What do we use as vectors?

- · Color (Red, Green, Blue)
 - Can be used, for example to reduce 24bits/ pixel to 8bits/pixel
 - Used in some terminals to reduce data rate from the CPU (colormaps)
- K consecutive samples in audio
- Block of K pixels in an image
 How do we decide on a codebook
- Typically done with clustering

Vector Quantization: Example

Page 6

Linear Transform Coding

Want to encode values over a region of time or space

- Typically used for images or audio

Select a set of linear basis functions ϕ_i that span the space

- sin, cos, spherical harmonics, wavelets, ...
- Defined at discrete points

Linear Transform Coding

Coefficients:
$$\Theta_i = \sum_j x_j \phi_i(j) = \sum_j x_j a_{ij}$$

$$\Theta_i = i^{th} \text{ resulting coefficient}$$

$$x_j = j^{th} \text{ input value}$$

$$a_{ij} = ij^{th} \text{ transform coefficient} = \phi_i(j)$$

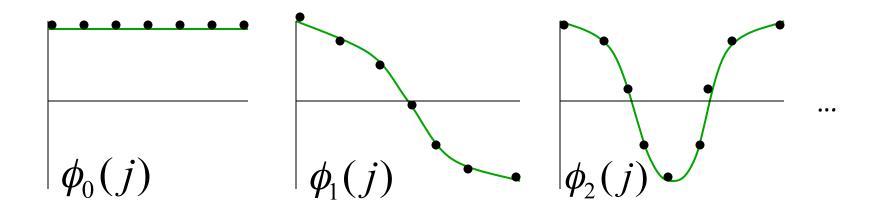

$$\Theta = Ax$$

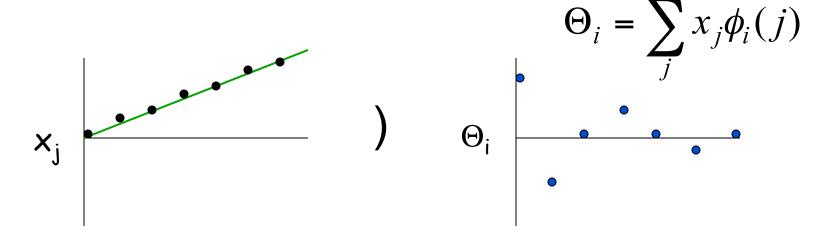

In matrix notation:

$$x = A^{-1}\Theta$$

Where A is an $n \times n$ matrix, and each row defines a basis function

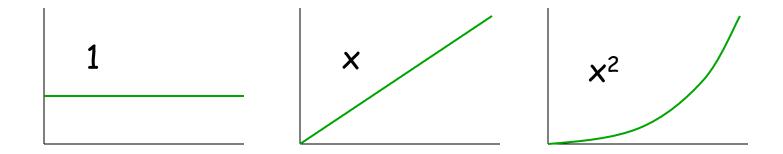

Example: Cosine Transform

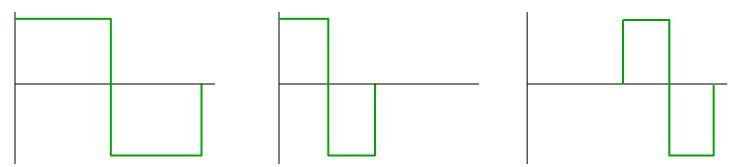

Other Transforms

Polynomial:

Wavelet (Haar):

How to Pick a Transform

Goals:

- Decorrelate
- Low coefficients for many terms
- Basis functions that can be ignored by perception

Why is using a Cosine of Fourier transform across a whole image bad?

How might we fix this?

Usefulness of Transform

Typically transforms A are <u>orthonormal</u>: $A^{-1} = A^{T}$ <u>Properties of orthonormal transforms</u>:

$$-\sum x^2 = \sum \Theta^2$$
 (energy conservation)

Would like to compact energy into as few coefficients as possible

$$G_{TC} = \frac{\frac{1}{n} \sum \sigma_i^2}{\left(\prod \sigma_i^2\right)^{1/n}}$$
 (the transform coding gain) arithmetic mean/geometric mean

$$\sigma_i = (\Theta_i - \Theta_{av})$$

The higher the gain, the better the compression

Case Study: JPEG

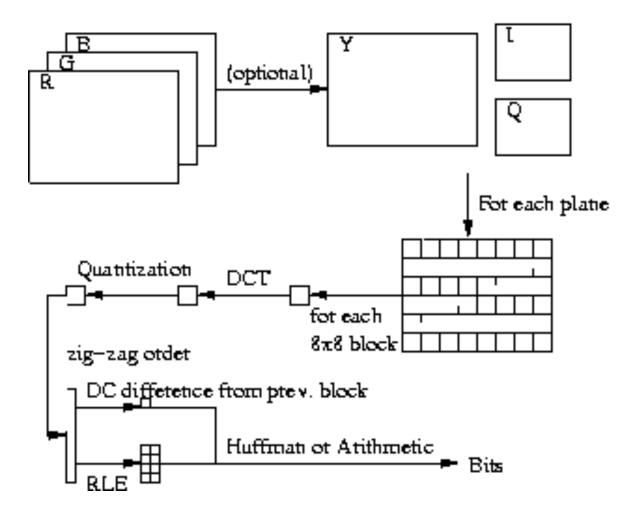

A nice example since it uses many techniques:

- Transform coding (Cosine transform)
- Scalar quantization
- Difference coding
- Run-length coding
- Huffman or arithmetic coding

JPEG (Joint Photographic Experts Group) was designed in 1991 for lossy and lossless compression of color or grayscale images. The lossless version is rarely used.

Can be adjusted for compression ratio (typically 10:1)

JPEG in a Nutshell

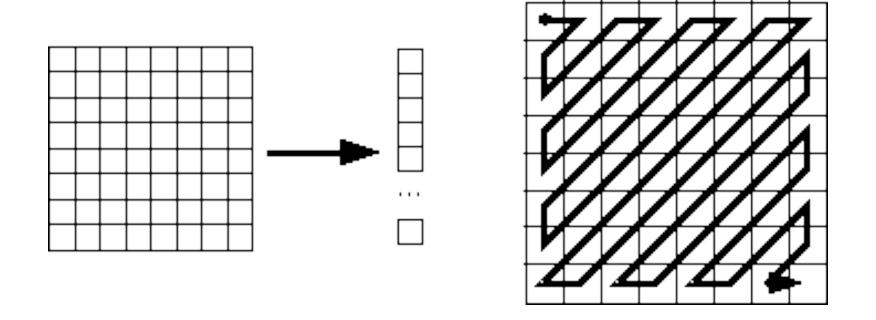

JPEG: Quantization Table

| 16 | 11 | 10 | 16 | 24 | 40 | 51 | 61 |
|----|----|----|----|-----|-----|-----|-----|
| 12 | 12 | 14 | 19 | 26 | 58 | 60 | 55 |
| 14 | 13 | 16 | 24 | 40 | 57 | 69 | 56 |
| 14 | 17 | 22 | 29 | 51 | 87 | 80 | 62 |
| 18 | 22 | 37 | 56 | 68 | 109 | 103 | 77 |
| 24 | 35 | 55 | 64 | 81 | 104 | 113 | 92 |
| 49 | 64 | 78 | 87 | 103 | 121 | 120 | 101 |
| 72 | 92 | 95 | 98 | 112 | 100 | 103 | 99 |

Also divided through uniformaly by a quality factor which is under control.

JPEG: Block scanning order

Uses run-length coding for sequences of zeros

JPEG: example

.125 bits/pixel (factor of 200)

Case Study: MPEG

Pretty much JPEG with interframe coding Three types of frames

- I = intra frame (aprox. JPEG) anchors
- P = predictive coded frames
- B = bidirectionally predictive coded frames

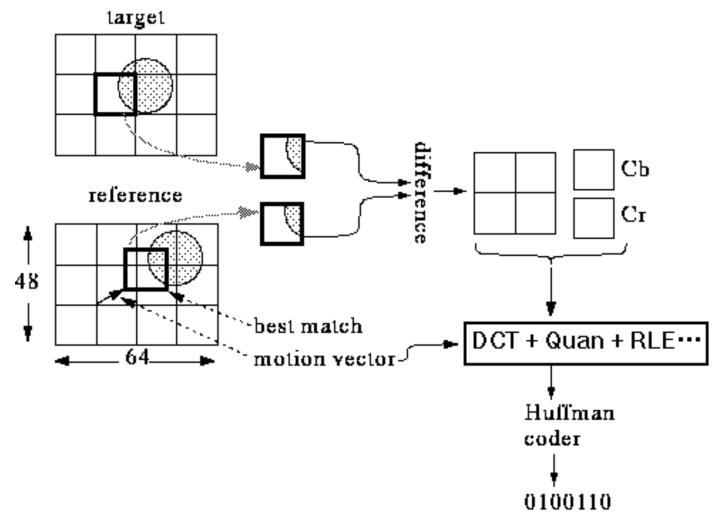

Example:

```
Type: I B B P B B P B B I

Order: 1 3 4 2 6 7 5 9 10 8 12 13 11
```

I frames are used for random access.

MPEG matching between frames

MPEG: Compression Ratio

356 x 240 image

| Type | Size | Compression | |
|---------|-------|-------------|--|
| I | 18KB | 7/1 | |
| Р | 6KB | 20/1 | |
| В | 2.5KB | 50/1 | |
| Average | 4.8KB | 27/1 | |

30 frames/sec x 4.8KB/frame x 8 bits/byte

= 1.2 Mbits/sec + .25 Mbits/sec (stereo audio)

HDTV has 15x more pixels

= 18 Mbits/sec

MPEG in the "real world"

- · DVDs
 - Adds "encryption" and error correcting codes
- Direct broadcast satellite
- HDTV standard
 - Adds error correcting code on top
- Storage Tech "Media Vault"
 - Stores 25,000 movies

Encoding is much more expensive than encoding.

Still requires special purpose hardware for high resolution and good compression.

Wavelet Compression

- A set of localized basis functions
- Avoids the need to block

"mother function" $\phi(x)$

$$\varphi_{sl}(x) = \varphi(2^s x - 1)$$

 $s = scale$ $l = location$

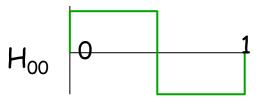

<u>Requirements</u>

$$\int_{-\infty}^{\infty} \varphi(x) dx = 0 \quad \text{and} \quad \int_{-\infty}^{\infty} |\varphi(x)|^2 dx < \infty$$

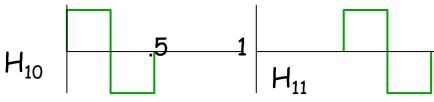

Many mother functions have been suggested.

Haar Wavelets

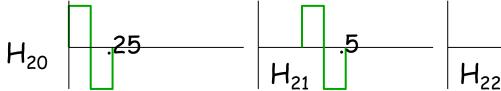

Most described, least used.

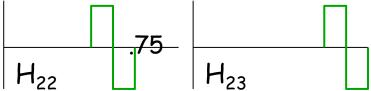

$$\varphi(x) = \begin{cases} 1 & 0 \le x < 1/2 \\ -1 & 1/2 \le x < 1 \\ 0 & \text{otherwise} \end{cases}$$

$$H_{sl}(x) = \phi(2^s x - 1)$$

 H_{k0} ...

+ DC component = 2^{k+1} components

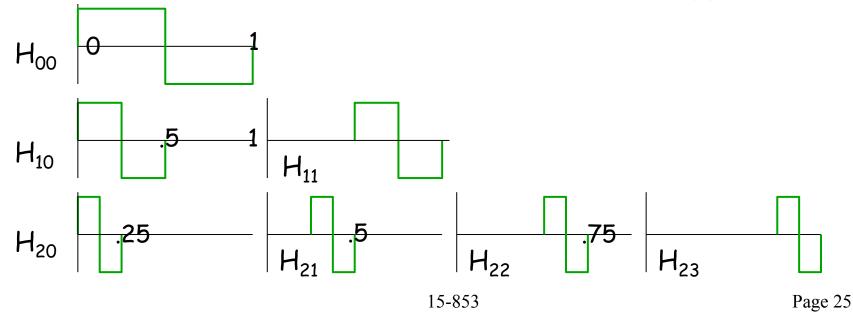

Haar Wavelet in 2d

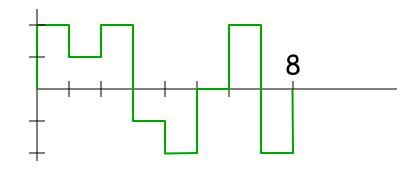

Discrete Haar Wavelet Transform

How do we convert this to the wavelet coefficients?

Discrete Haar Wavelet Transform

How do we convert this to the wavelet coefficients?

```
for (j = n/2; j >= 1; j = j/2) {
  for (i = 1; i < j; i++) {
     Averages

  b[i] = (a[2i-1] + a[2i])/2;

  b[j+i] = (a[2i-1] - a[2i])/2; }

a[1..2*j] = b[1..2*j]; }

Differences</pre>
```

Linear time!

Haar Wavelet Transform: example

```
a = 2 1 2 -1 -2 0 2 -2

= 1.5 .5 -1 0 .5 1.5 -1 2

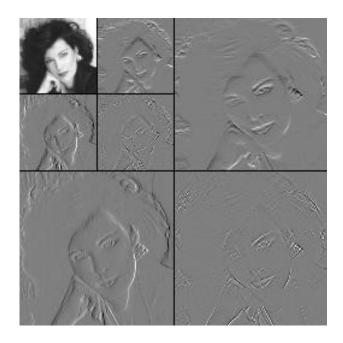

= 1 -.5 .5 -.5

= .25 .75

a = .25 .75 .5 .5 .5 1.5 -1 2
```

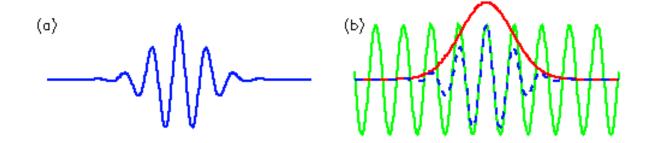

Wavelet decomposition

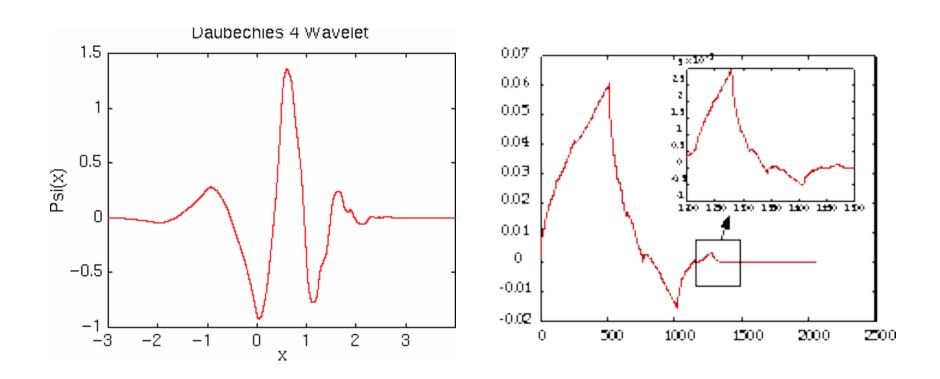

Morlet Wavelet

$$\phi(x) = Gaussian \times Cosine = e^{-(x^2/2)}cos(5x)$$

Corresponds to wavepackets in physics.

Daubechies Wavelet

JPEG2000

Overall Goals:

- High compression efficiency with good quality at compression ratios of .25bpp
- Handle large images (up to $2^{32} \times 2^{32}$)
- Progressive image transmission
 - Quality, resolution or region of interest
- Fast access to various points in compressed stream
- Pan and Zoom while only decompressing parts
- Error resilience

JPEG2000: Outline

Main similarities with JPEG

- Separates into Y, I, Q color planes, and can downsample the I and Q planes
- Transform coding

Main differences with JPEG

- Wavelet transform
 - Daubechies 9-tap/7-tap (irreversible)
 - Daubechies 5-tap/3-tap (reversible)
- Many levels of hierarchy (resolution and spatial)
- Only arithmetic coding

JPEG2000: 5-tap/3-tap

```
h[i] = a[2i-1] - (a[2i] + a[2i-2])/2;

l[i] = a[2i] + (h[i-1] + h[i] + 2)/2;
```

h[i]: is the "high pass" filter, ie, the differences it depends on 3 values from a (3-tap)

1[i]: is the "low pass" filter, ie, the averages it depends on 5 values from a (5-tap)

Need to deal with boundary effects.

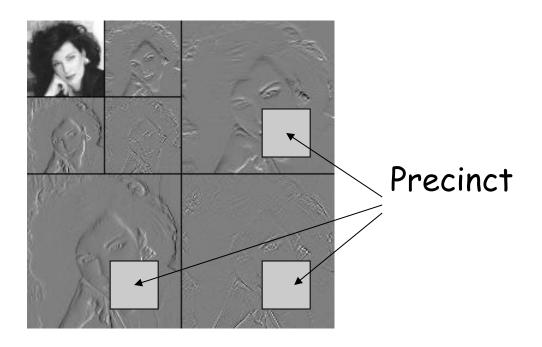

This is reversible: assignment

JPEG 2000: Outline

A spatial and resolution hierarchy

- Tiles: Makes it easy to decode sections of an image. For our purposes we can imagine the whole image as one tile.
- Resolution Levels: These are based on the wavelet transform. High-detail vs. Low detail.
- Precinct Partitions: Used within each resolution level to represent a region of space.
- Code Blocks: blocks within a precinct
- Bit Planes: ordering of significance of the bits

JPEG2000: Precincts

JPEG vs. JPEG2000

JPEG: .125bpp

JPEG2000: .125bpp

Compression Outline

Introduction: Lossy vs. Lossless, Benchmarks, ...

Information Theory: Entropy, etc.

Probability Coding: Huffman + Arithmetic Coding

Applications of Probability Coding: PPM + others

Lempel-Ziv Algorithms: LZ77, gzip, compress, ...

Other Lossless Algorithms: Burrows-Wheeler

Lossy algorithms for images: JPEG, MPEG, ...

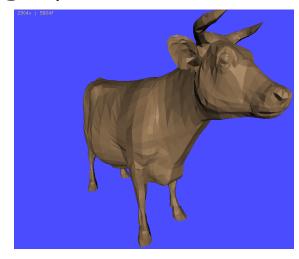

Compressing graphs and meshes: BBK

Compressing Structured Data

So far we have concentrated on Text and Images, compressing sound is also well understood.

What about various forms of "structured" data?

- Web indexes
- Triangulated meshes used in graphics
- Maps (mapquest on a palm)
- XML
- Databases

Compressing Graphs

<u>Goal</u>: To represent large graphs compactly while supporting queries efficiently

- e.g., adjacency and neighbor queries
- want to do significantly better than adjacency lists (e.g. a factor of 10 less space, about the same time)

Applications:

- Large web graphs
- Large meshes
- Phone call graphs

How to start?

Lower bound for n vertices and m edges?

- 1. If there are N possible graphs then we will need log N bits to distinguish them
- 2. in a directed graph there are n² possible edges (allowing self edges)
- 3. we can choose any m of them so $N = (n^2 \text{ choose m})$
- 4. We will need log $(n^2 \text{ choose m}) = O(m \log (n^2/m))$ bits in general

For sparse graphs (m = kn) this is hardly any better than adjacency lists (perhaps factor of 2 or 3).

What now?

Are all graphs equally likely?

Are there properties that are common across "real world" graphs?

Consider

- link graphs of the web pages
- map graphs
- router graphs of the internet
- meshes used in simulations
- circuit graphs

LOCAL CONNECTIONS / SMALL SEPARATORS

Edge Separators

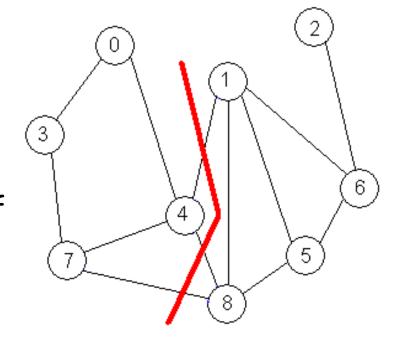

An <u>edge separator</u> for (V,E) is a set of edges E' ½ E whose removal partitions V into two components V_1 and V_2

Goals:

- balanced ($|V_1| \frac{1}{4} |V_2|$)
- small (|E'| is small)

A class of graphs S satisfies a $\underline{f(n)\text{-}edge\ separator\ theorem}$ if $9\alpha < 1$, $\beta > 0$ 8 (V,E) 2 S, 9 separator E', $|E'| < \beta\ f(|V|)$, $|V_i| < \alpha |V|$, i = 1,2

Can also define <u>vertex separators</u>.

Separable Classes of Graphs

Planar graphs: $O(n^{1/2})$ separators

Well-shaped meshes in R^d : $O(n^{1-1/d})$ [Miller et al.]

Nearest-neighbor graphs

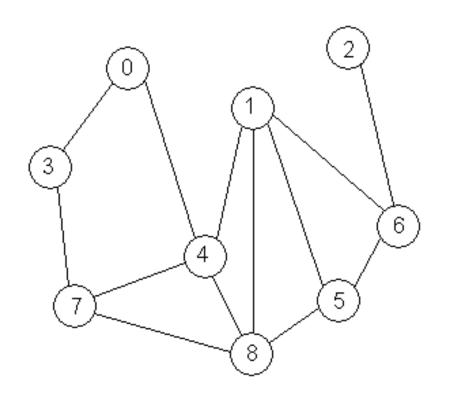

In practice, good separators from circuit graphs, street graphs, web connectivity graphs, router connectivity graphs

Note: All separable classes of graphs have bounded density (m is O(n))

Main Ideas

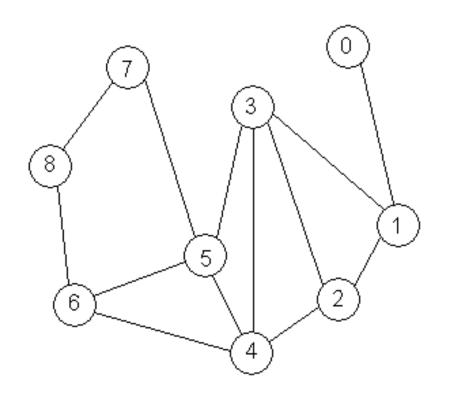

- Number vertices so adjacent vertices have similar numbers
 - Use separators to do this
- Use difference coding on adjacency lists
- Use efficient data structure for indexing

Compressed Adjacency Tables

| # | D | Neighbors | | | | Dif | fer | en | ces |
|---|---|-----------|---|---|---|-----|-----|----|-----|
| 0 | 2 | 3 | 4 | | | 3 | 1 | | |
| 1 | 4 | 4 | 5 | 6 | 8 | 3 | 1 | 1 | 2 |
| 2 | 1 | 6 | | | | 4 | | | |
| 3 | 2 | 0 | 7 | | | -3 | 7 | | |
| 4 | 4 | 0 | 1 | 7 | 8 | -4 | 1 | 6 | 1 |
| 5 | 3 | 1 | 6 | 8 | | -4 | 5 | 2 | |
| 6 | 3 | 1 | 2 | 5 | | -5 | 1 | 3 | |
| 7 | 3 | 3 | 4 | 8 | | -4 | 1 | 4 | |
| 8 | 4 | 1 | 4 | 5 | 7 | -7 | 3 | 1 | 2 |

Compressed Adjacency Tables

| # | D | Neighbors | | | | Dif | fer | er | ice | s |
|---|---|-----------|---|---|---|-----|-----|----|-----|---|
| 0 | 1 | 1 | | | | 1 | | | | |
| 1 | 3 | 0 | 2 | 3 | | -1 | 2 | 1 | | |
| 2 | 3 | 1 | 3 | 4 | | -1 | 2 | 1 | | |
| 3 | 4 | 1 | 2 | 4 | 5 | -1 | 1 | 2 | 1 | |
| 4 | 4 | 2 | 3 | 5 | 6 | -2 | 1 | 2 | 1 | |
| 5 | 4 | 3 | 4 | 6 | 7 | -2 | 1 | 2 | 1 | |
| 6 | 3 | 4 | 5 | 8 | | -2 | 1 | 3 | | |
| 7 | 2 | 5 | 8 | | | -2 | 3 | | | |
| 8 | 2 | 6 | 7 | | | -2 | 1 | | | |

Log-sized Codes

Log-sized code: Any prefix code that takes O(log (d)) bits to represent an integer d.

Gamma code, delta code, skewed Bernoulli code

| Example: Gamma code |
|--|
| Prefix: unary code for [log d] |
| Suffix: binary code for d-2[log d] |
| (binary code for d, except leading 1 is implied) |

| Decimal | Gamma | | | |
|---------|-------|-----|--|--|
| 1 | 1 | | | |
| 2 3 | 01 | 0 | | |
| 3 | 01 | 1 | | |
| 4 | 001 | 00 | | |
| 5 | 001 | 01 | | |
| 6 | 001 | 10 | | |
| 7 | 001 | 11 | | |
| 8 | 0001 | 000 | | |

Difference Coding

For each vertex, encode:

- Degree
- Sign of first entry
- Differences in adjacency list

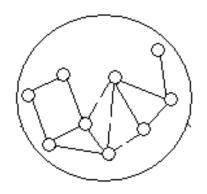

Concatenate vertex encodings to encode the graph

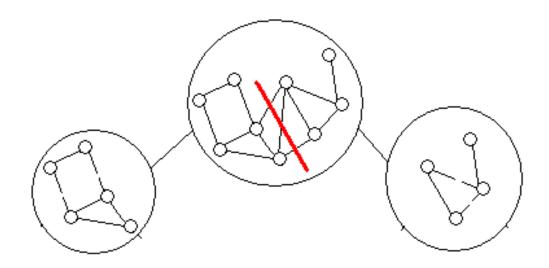

| # | | Differences |
|---|---|-------------|
| 0 | 2 | 3 1 |

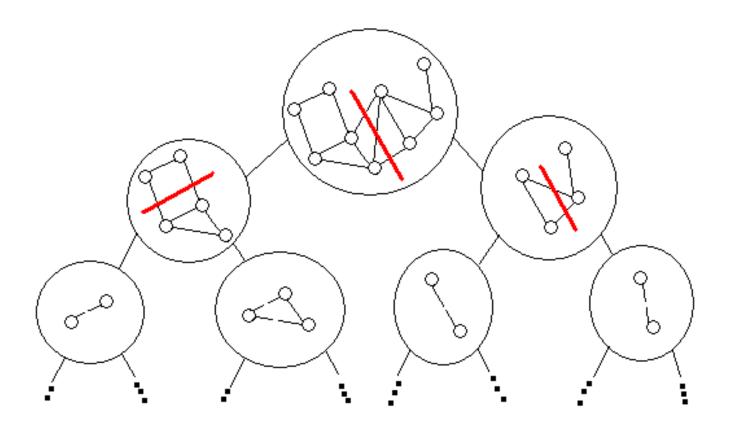

010 0 011 1 degree sign 3 1

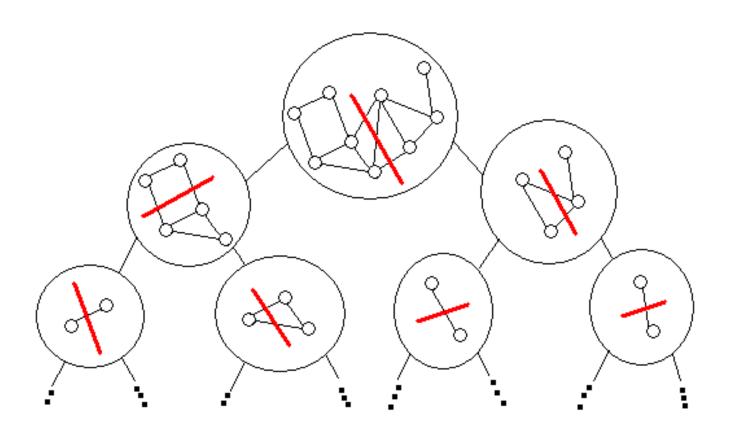

| # | D | Differences | | | | | |
|---|---|-------------|--|--|--|--|--|
| 4 | 4 | -4 1 6 1 | | | | | |

00100 1 00100 1 00110 1 degree sign 4 1 6 1

Theorem (edge separators)

Any class of graphs that allows $O(n^c)$ edge separators can be compressed to O(n) bits with O(1) access time using:

- Difference coded adjacency lists
- O(n)-bit indexing structure

Performance: Adjacency Table

time is for one DFS

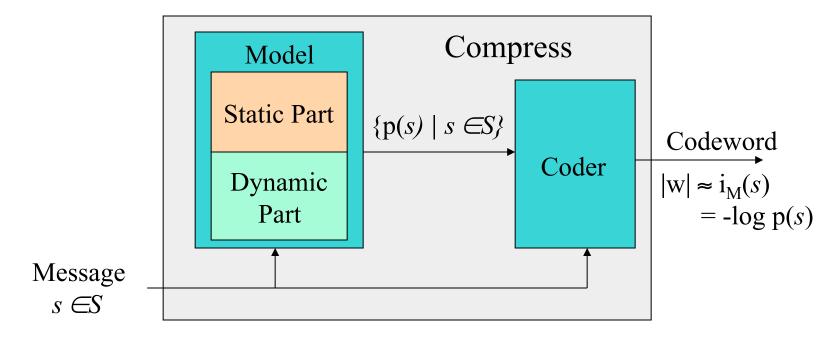

Conclusions

O(n)-bit representation of separable graphs with O(1)-time queries

Space efficient and fast in practice for a wide variety of graphs.

Compression Summary

Compression is all about probabilities

We want the model to skew the probabilities as much as possible (i.e., decrease the entropy)

Compression Summary

How do we figure out the probabilities

- Transformations that skew them
 - Guess value and code difference
 - Move to front for temporal locality
 - Run-length
 - Linear transforms (Cosine, Wavelet)
 - Renumber (graph compression)
- Conditional probabilities
 - Neighboring context

In practice one almost always uses a combination of techniques
